Below is the latest documentation for CTR-Electronics Phoenix software framework. This includes...

- **Class library** for supported Phoenix devices for programming in C++, Java (FRC), LabVIEW (FRC), or C# (HERO).
- **Phoenix Tuner** Graphical Interface - provides configuration options, diagnostics, control and plotting.
- **Phoenix Diagnostic Server** - install on to roboRIO for Tuner, and to perform HTTP API requests for diagnostic information.

Blog Entries

Blog entries for 2022 and on will be posted at: [CTR-Electronics Blog](#).

Follow these instructions in order!

2.1 Phoenix Software Reference Manual

This is the latest documentation for CTR-Electronics Phoenix software framework. This includes:

- 1) Class library for supported Phoenix devices for programming in C++, Java (FRC), LabVIEW (FRC), or C# (HERO).
- 2) Phoenix Tuner GUI - provides configuration options, diagnostics, control and plotting.
- 3) Phoenix Diagnostic Server - install on to RIO for Tuner, and to perform HTTP API requests for diagnostic information.
- 4) Supplemental CLI commands for roboRIO-Linux.

Be sure to follow the following instructions in order to ensure success in developing your robot platform.

2.2 Primer: CTRE CAN Devices

CTR-Electronics has designed many of the available CAN bus devices for FRC-style robotics. This includes:

- Motor Controllers such as Talon FX, Talon SRX, and Victor SPX
- Orientation devices such as Pigeon IMU and Pigeon 2.0
- Sensors such as CANcoder and CANifier
- Full list of Phoenix devices
- Pneumatics Control Mode (PCM)
- Power Distribution Panel (PDP)

These devices have similar functional requirements, specifically every device of a given model group requires a unique device ID for typical FRC use (settings, control and status). The device ID is usually expressed as a number between '0' and '62', allowing use for up to 63 Talon SRXs, 63 Victors, 63 PDPs, etc. at once. This range does not intersect with device IDs of other CAN device types. For example, there is no harm in having a Pneumatics Control

Module (PCM) and a Talon SRX both with device ID '0'. However, having two Talon SRXs with device ID '0' will be problematic.

These devices are field upgradable, and the firmware shipped with your devices will pre-date the “latest and greatest” tested firmware intended for use with the latest API release. Firmware update can be done easily using Phoenix Tuner.

The Talon FX/SRX and Victor SPX provide two pairs of twisted CANH (yellow) and CANL (green) allowing for daisy chaining. Other devices such as the PDP and PCM have Weidmuller connectors that accept twisted pair cabling. Often you will be able to use your Talons and Victors to connect together your PCM and PDP to each other.

The CAN termination resistors are built into the FRC robot controller (roboRIO) and in the Power Distribution Panel (PDP) assuming the PDP's termination jumper is in the ON position.

More information on wiring and hardware requirements can be found in the user manual of each device type.

2.3 Primer: What is Phoenix v5 Software

Phoenix is a package that targets LabVIEW, C++, and Java for the FRC Robotics Controller platform, i.e. the NI roboRIO robot controller.

It includes the Application Programming Interface (API), which are the functions you call to manipulate Phoenix devices on the CAN bus.

Note: PCM and PDP API are built into the core WPI distribution.

The C++ and Java APIs are very similar, typically only differing on the function name case (configAllSettings in Java versus ConfigAllSettings in C++). Because Java is more widely used in FRC than C++, this document will reference the Java routine names. C++ users should take note that the leading character of every function is UPPERCASE in C++.

Additionally, Phoenix shared libraries are also targeted for C++ on Linux (amd64, armhf, aarch64) and typically available on our maven repository. The example support libraries use socket-can for CANBus access, however custom drivers can be provided by the end user for alternative CANBus solutions (NVIDIA TX2 native CAN bus for example).

Phoenix also includes a NETMF (C#) class library for the non-FRC HERO Robot Controller. This can replace the roboRIO in use cases that don't require the full features of the FRC control system, and are not in use during competition.

Note: With Phoenix framework, teams can control/leverage Phoenix devices outside of the roboRIO (e.g. Rasp-Pi or Jetson TX2), and use the roboRIO/DriverStation to safely enable/disable the actuators.

Note: Leveraging CTRE CAN devices from third-party CAN hardware was officially made FRC legal for the **2019 season**.

There are tons of examples in all languages at CTRE's GitHub account:

- <https://github.com/CrossTheRoadElec/Phoenix-Examples-Languages>

- <https://github.com/CrossTheRoadElec/Phoenix-Examples-LabVIEW>

Entire GitHub organization: <https://github.com/CrossTheRoadElec/>

Phoenix-Examples-Languages and Phoenix-Examples-LabVIEW are specifically tested on the FRC RoboRIO control system.

Phoenix-Linux-SocketCAN-Example demonstrates control of Talons from a Raspberry Pi. <https://github.com/CrossTheRoadElec/Phoenix-Linux-SocketCAN-Example>

2.3.1 What is Phoenix Tuner?

Phoenix-Tuner v1 is the graphical interface that allows for configuration of Phoenix CAN bus devices.

Tip: There is a modernized version called [Tuner X](#) that is available for Windows and Android devices (works with Phoenix 5 and [Phoenix Pro](#)).

It provides a variety of functionality to support all Phoenix CAN Bus devices. The feature set includes:

- Update device firmware (including PDP/PCM)
- Change CAN IDs
- Configure direction and offsets

- Self-test Snapshot devices
- Change configuration settings
- Factory default configuration settings
- Test motors
- Check plots
- Temperature Calibrate Pigeon-IMU
- Confirm proper CAN bus wiring **without writing any software.**

Now you can drive your motors and collect data *without writing any software.*

Configuration values can be **checked, modified, and defaulted** with the new config view. Config values can also be **imported/exported** as an easy-to-follow JSON formatted file.

The following sections of documentation will cover how to use Phoenix Tuner and the other components of Phoenix.

Tip: Have a feature request? Send to us at support@ctr-electronics.com or report it on GitHub.

2.4 Do I need to install any of this?

Yes, if any of the following:

- **You need library support for:**
 - CANcoder
 - CAnDle
 - CANifier
 - CANivore USB-to-CAN Adapter
 - Falcon 500 Powered by Talon FX

- Pigeon IMU
 - Pigeon 2.0
 - Talon SRX
 - Victor SPX
- You need to field upgrade [PCM](#), [PDP](#), or any of the above devices
 - You want to use Phoenix Tuner for CAN diagnostics (highly recommended)

Note: [PCM](#) and [PDP](#) objects are already supported in the base FRC installation. However, Phoenix Tuner is required for setting the device ID, field-upgrade, and Self-test Snapshot.

2.5 Prepare your workstation computer

2.5.1 Before Installing Phoenix...

It is strongly recommended to complete the base installation of FRC tools. <https://docs.wpilib.org/en/latest/docs/getting-started/getting-started-frc-control-system/control-system-software.html>

Warning: You will need to image the roboRIO to latest software before continuing. See FRC/NI documentation on [how to image the roboRIO](#).

Test base FRC Installation - FRC LabVIEW

If a team intends to use LabVIEW to develop robot software, be sure to complete the full NI installer. At which point, opening LabVIEW should reveal the FRC-styled graphical start menu.

At this point it is recommended to create a simple template project and test deploy to the roboRIO. Be sure the DriverStation can communicate with the robot controller, and that DS message log is functional.

Test base FRC Installation - FRC C++ / Java

It is recommended to install the FRC Driver Station Utilities. This will install the Driver Station software, which is necessary for:

1. Basic comms checks
2. Reading joystick data
3. Generally required for enabling motor actuation (Phoenix Tuner Control features may require this, depending on setup).

General Recommendations for FRC C++ / Java.

The FRC C++/Java standard distribution for 2020 is based on the Microsoft Visual Studio Code development environment with WPI extensions.

If you are not familiar with developing C++/Java FRC programs, we strongly recommend testing full deployment to your robot controller before installing Phoenix and porting previous season software. A recommended test is to:

1. Create a project from scratch
2. Make a simple change such as add a print statement with a counter.
3. Deploy (or debug) your application.
4. Confirm robot can be teleop-enabled in DS.
5. Open FRC message Console and read through all the messages.
6. Repeat 2 - 5 ten times. This will train students to become familiar with and build general confidence in the tools.

Note: Third-party vendor libraries are installed into the C++/Java project, not the environment. For each C++/Java project you create, you must use the WPI provided tools to select Phoenix to bring the libraries into your project.

2.5.2 What to Download (and why)

Option 1: Windows installer (strongly recommended)

Environments: Windows-LabVIEW, Windows-C++/Java, HERO C#

Phoenix Installer zip can be downloaded at: <https://store.ctr-electronics.com/software/>.

It is typically named Phoenix Framework_Windows_vW.X.Y.Z.zip

This will install:

- The LabVIEW Phoenix API (if LabVIEW is detected and selected in installer)
- The C++/Java Phoenix API (if selected in installer)
- Device Firmware Files (that were tested with the release)
- CTRE Support of RobotBuilder
- Phoenix Tuner
 - Installs Phoenix API libraries into the roboRIO (required for LabVIEW)
 - Installs Phoenix Diagnostics Server into the RoboRIO (needed for CAN diagnostics).
 - Plotter/Control features
 - Self-test Snapshot
 - Device ID and field-upgrade

Warning: If using Microsoft Edge, the browser may flag the download for security reasons. In the menu bar of the downloaded file, select “Keep”.

If the browser asks, confirm the download is trustworthy.

Option 2: Phoenix API via Non-Windows Zip

Environments: Linux/MacOS - C++/Java

The Phoenix API can be manually installed on non-Windows platforms by downloading the “non-Windows” zip and following the instructions found inside.

This essentially contains a maven-style repository that holds the API binaries and headers, as well as a “vendordeps” JSON file that instructs VS how to incorporate the Phoenix C++/Java API libraries.

Note: This is auto installed when using the Windows full installer (Option 1).

Phoenix Tuner

Environments: Windows

If you are using option 2, you will need to download Phoenix Tuner separately. Phoenix Tuner is available here... <https://github.com/CrossTheRoadElec/Phoenix-Tuner-Release/releases>

This can be convenient for workstations that aren’t used for software development, but are used for field-upgrade or testing motor controllers.

Note: LabVIEW teams may need to use Phoenix Tuner to install Phoenix libraries into the roboRIO. More information on this can be found under Prepare Robot Controller.

Note: This is auto installed when using the Windows full installer.

Note: Developers may be interested to know that all Phoenix Tuner features leverage an HTTP API provided by the Phoenix Diagnostics Server. As such, custom tooling can be developed to field-upgrade, test-control, or diagnostics CTRE devices without Tuner.

Device Firmware Files (crf)

The test firmware files for all CTRE devices are packaged with the Windows Installer (and has been for years). However, many FRC teams don’t notice, or prefer to download them directly from the product pages on the ctr-electronics.com website. If Internet access is available, they can be downloaded as such.

The FRC Software installer will create a directory with various firmware files/tools for many control system components. Typically, the path is:

`C:\Users\Public\Documents\FRC`

When the path is entered into a browser, the browser may fix-up the path:

`C:\Users\Public\Public Documents\FRC`

In this directory are the initial release firmware CRF files for all CTRE CAN bus devices, including the new Talon FX and CANCoder.

The latest firmware to be used can be found in the [Software Release Notes](#).

Note: Additionally, newer updates may be provided online at <https://store.ctr-electronics.com/software/>.

Note: There is no longer FRC versus non-FRC firmware for motor controllers. Instead the latest firmware detects if the use case is FRC. If so, the device will FRC-Lock, and will require the Driver Station for actuation.

2.5.3 Workstation Installation

There are two installation methods listed below. The simplest and recommended approach is to run the Windows Installer (Option 1).

Option 1: Windows Offline Installer (C++/Java/LabVIEW, HERO C#)

Un-compress the downloaded zip.

Double click on the installer. If the Windows protection popup appears press More Info, then Run anyway.

This will look very similar to previous installers - make sure you have the relevant component selected for your programming language.

LV Teams: Make sure LabVIEW is selected. If it is grayed out, then LabVIEW was not installed on the PC.

C++/Java Teams: Make sure C++/Java is selected.

If Visual Studio 2017 (Community/Professional) is detected, HERO C# will be selected. This can be turned off to speed up the installer.

Installer can take anywhere from 30 seconds to 5 minutes depending on which Microsoft runtimes need to be installed.

Final page will look like this. The Phoenix Tuner link can be used to open Phoenix Tuner. Alternatively, you can use the Windows Start Menu.

Option 2: Non-Windows Zip (C++/Java)

The zip will contain **two folders**, “**maven**” and “**vendordeps**”. These folders are meant to be **inserted into your frc2020 install folder**.

See WPI documentation for typical location. <https://docs.wpilib.org/en/latest/docs/software/wpilib-overview/3rd-party-libraries.html#the-mechanism-c-java>

Copy/paste the maven and vendordeps folder into frc2020 folder. This will override a pre-existing Phoenix installation if present.

Note: This will not install Phoenix Tuner or firmware files. If these are necessary (and they typically are) these can be downloaded separately or consider using the complete Phoenix Installer.

2.5.4 Post Installation Steps

After all workstation installs, the following checks should be followed to confirm proper installation.

FRC C++/Java - Verify Installation

The offline files for vscode are typically installed in:

```
C:\Users\Public\wpilib\2020\vendordeps\Phoenix.json (File used by vscode to include
↳ Phoenix in your project)
C:\Users\Public\wpilib\2020\maven\com\ctre\phoenix (multiple maven-style library
↳ files)
```

Your drive letter may be different than "C:". After running the Phoenix Installer, the instructions to add or update Phoenix in your robot project must be followed.

FRC LabVIEW - Verify Installation

After running the installer, open a pristine copy of FRC LabVIEW.

Testing the install can be done by opening LabVIEW and confirming the VIs are installed. This can be done by opening an existing project or creating a new project, or opening a single VI in LabVIEW. Whatever the simplest method to getting to the LabVIEW palette.

The CTRE Palette is located in:

- WPI Robotics Library -> Third Party.

This palette can also be found in:

- WPI Robotics Library -> RobotDrive -> MotorControl -> CanMotor
- WPI Robotics Library -> Sensors -> Third Party
- WPI Robotics Library -> Actuators -> Third Party

Warning: LabVIEW teams not using latest Phoenix may need to chain Phoenix Open VIs together. See the errata here: [LabVIEW Phoenix Open VIs must be chained to guarantee sequential execution](#)

FRC Windows - Open Phoenix Tuner

Open Phoenix Tuner

If this is the first time opening application, confirm the following:

- the status bar should read “Lost Comm”.
- No CAN devices will appear.
- The Server version will be unknown.

2.6 FRC: VS Code C++/Java

2.6.1 FRC C++/Java - Create a Project

Next we will create a new robot project in vscode and create a Talon SRX. The goal is compile the project only, so hardware is not needed.

Follow the WPI frc-docs instructions on reaching the create new project. Typically, you can use CNTRL+SHIFT+P to open the VS text bar, and type create to reach the WPI command.

“Timed Skeleton” is used in this example for sake of simplicity.

WPIlib Project Creator x

Welcome to WPIlib New Project Creator

template cpp Timed Skeleton (Advanced)

Select a folder to place the new project into.

c:\temp\workspace

Select a new project folder

Create new folder? Highly recommended to be checked ☒

Enter a project name

MyCppProject

Enter a team number

217

This is needed for simulation and unit testing support, however there are some cases where command "WPIlib: Set Desktop Support" at any time. ☐

Generate Project

WPILib Project Creator x

Welcome to WPILib New Project Creator

template java Timed Skeleton (Advanced)

Select a folder to place the new project into.

c:\temp\workspace

Select a new project folder

Create new folder? Highly recommended to be checked ☒

Enter a project name

MyJavaProject

Enter a team number

217

This is needed for simulation and unit testing support, however there are some cases where command "WPILib: Set Desktop Support" at any time. ☐

Generate Project

Once the project is created, ensure project builds. Testing robot deploy is also useful if robot controller is available.

2.6.2 FRC C++/Java - Add Phoenix

Right-Click on “build.gradle” in the project tree, then select “Manage Vendor Libraries”.

At the top of your screen, a menu will appear. Select “Install new libraries (offline)”.

Tip: Alternatively you can use “Install new libraries (online)” option with <https://maven.ctr-electronics.com/release/com/ctre/phoenix/Phoenix5-frc2023-latest.json>. However this is **not recommended** as this requires a live Internet connection to use your FRC project.

The menu will now display a list of vendor libraries you can install. Check “CTRE Phoenix”, then click “OK”

Note: This will bring the library into the project references, however the library will not be loaded if the source code does not create a Phoenix object or call any Phoenix routines. Therefore, you must create a Phoenix object to properly test the install.

Tip: Teams can verify Phoenix is in their robot project by checking for the existence of vendordeps/Phoenix.json in the project directory.

2.6.3 FRC C++ Build Test: Single Talon

Create a TalonSRX object. The number specified is the Talon’s device ID, however for this test, the device ID is irrelevant.

Be sure to include “ctre/Phoenix.h”, otherwise TalonSRX will not be recognized as a valid class type.

Add an example call, take your time to ensure to spell it correctly.

```
7
8  #include "Robot.h"
9
10 #include "ctre/Phoenix.h"
11
12  TalonSRX srx = {0};
13
14  void Robot::RobotInit() {
15      srx.Set(ControlMode::PercentOutput, 0);
16  }
17
18
19  void Robot::AutonomousInit() {}
```

Intellisense may not be functional at this point in time (note the green underline indicating VS did not parse the header).

Tip: To correct this - Close all files in the project - Restart VS Code - Wait ~40s - Reopen source files in VS Code

If you see linker errors, then the desktop simulation checkbox was likely checked.

The screenshot shows a VS Code editor with three tabs: 'build.gradle', 'Robot.cpp', and 'WPILib Help'. The 'Robot.cpp' tab is active, displaying the following code:

```

1  /* Open source software may be modified and shared by the team. The code
2  3  4  /* must be accompanied by the FIRST BSD license file in the root directory of */
5  /* the project. */
6  /*-----*/
7
8  #include "Robot.h"
9
10 #include "ctre/Phoenix.h"
11
12 TalonSRX srx = {0};
13
14 void Robot::RobotInit() {
15
16     srx.Set(ControlMode::PercentOutput, 0);
17 }
18
19 void Robot::AutonomousInit() {}
20 void Robot::AutonomousPeriodic() {}
21
22 void Robot::TeleopInit() {}
23 void Robot::TeleopPeriodic() {}
24
25 void Robot::TestInit() {}

```

Below the code editor, the 'TERMINAL' tab is active, showing the following build errors:

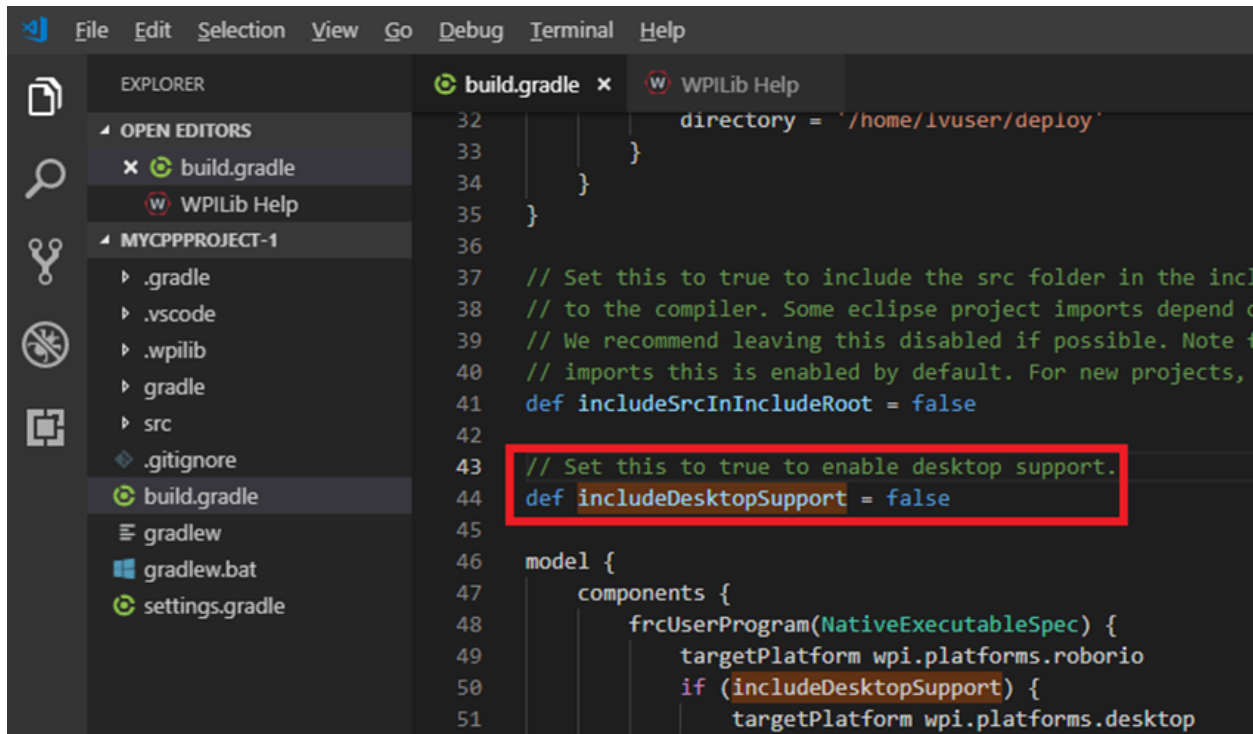

```

hoenix::platform::can::CANBusManager::GetRx(unsigned int,unsigned __int64 *,unsigned char &,unsigned in
I_N@Z)
CTRE_PhoenixCCI.lib(CANBusManager.obj) : error LNK2019: unresolved external symbol "int __cdecl ctre::p
us@can@platform@phoenix@ctre@@YAHPEAX@Z" referenced in function "private: void __cdecl ctre::phoenix::p
er@can@platform@phoenix@ctre@@AEAAXXZ"
CTRE_PhoenixCCI.lib(CANBusManager.obj) : error LNK2019: unresolved external symbol "void __cdecl ctre:
ortError@platform@phoenix@ctre@@YAXHHPBED00@Z" referenced in function "private: void __cdecl ctre::pho
td::char_traits<char>,class std::allocator<char> > &,bool)" (?LogStream@CANBusManager@can@platform@phoe
Z)
CTRE_PhoenixCCI.lib(TimestampMsgMap.obj) : error LNK2001: unresolved external symbol "void __cdecl ctre:
eportError@platform@phoenix@ctre@@YAXHHPBED00@Z"
C:\temp\workspace\MyCppProject-1\build\exe\frUserProgram\windowsx86-64\debug\frUserProgram.exe : fatal

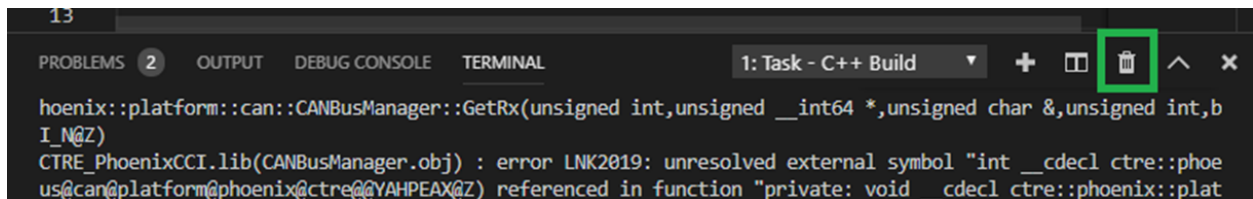

```

At the bottom of the terminal, a red message states: **FAILURE: Build failed with an exception.**

This can be resolved by manually turning off the feature. Set flag to false.

Tip: When resolving compiler/linker errors, press the trash icon first to cleanly erase the previous error lines in the terminal. Or manually scroll the bottom to ensure you are not looking at stale error lines from previously failed builds.

The only reliable way to confirm build was successful is to confirm the BUILD SUCCESSFUL line at the bottom of the TERMINAL.

Note: The problems tab may or may not be clear of errors. Our testing with VSCode has shown that it can report stale or incorrect information while making code changes. Always use the TERMINAL output to determine the health of your compilation and build system.

```

Robot.cpp x WPILib Help
1  // Open Source Software - may be modified and shared by the team. The code
2  // must be accompanied by the FIRST BSD license file in the root directory of */
3  // the project. */
4  /*-----*/
5
6  #include "Robot.h"
7
8  #include "ctre/Phoenix.h"
9
10 TalonSRX srx = {0};
11
12 void Robot::RobotInit() {
13
14     srx.Set(ControlMode::PercentOutput, 0);
15 }
16
17 void Robot::AutonomousInit() {}
18 void Robot::AutonomousPeriodic() {}
19
20 void Robot::TeleopInit() {}
21 void Robot::TeleopPeriodic() {}
22
23 void Robot::TestInit() {}
24
25

```

PROBLEMS 2 OUTPUT DEBUG CONSOLE TERMINAL

13
14 void Robot::RobotInit()
15 {
16     srx.SetInverted()
```

void
SetInverted(ctre::phoenix::motorcontrol::InvertType
invertType)

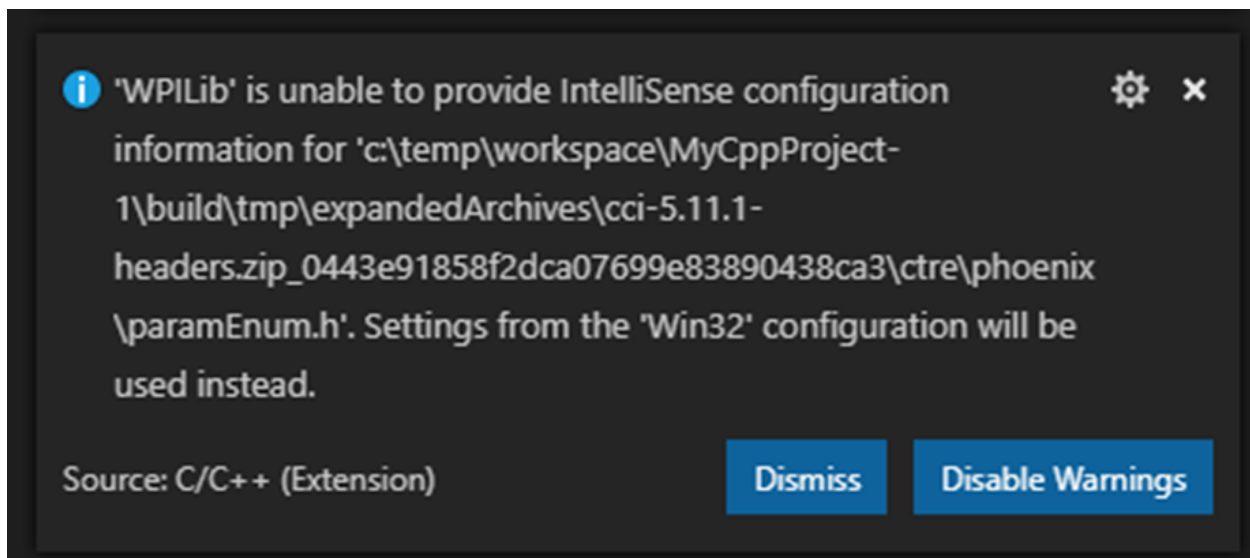

Tip: Headers can be auto-opened by CNTRL+CLICK the include line.

```
6  /*-----*/
7
8  #include "Robot.h"
9
10 #include "ctre/Phoenix.h"
```

#pragma once
#ifndef Phoenix_No_WPI

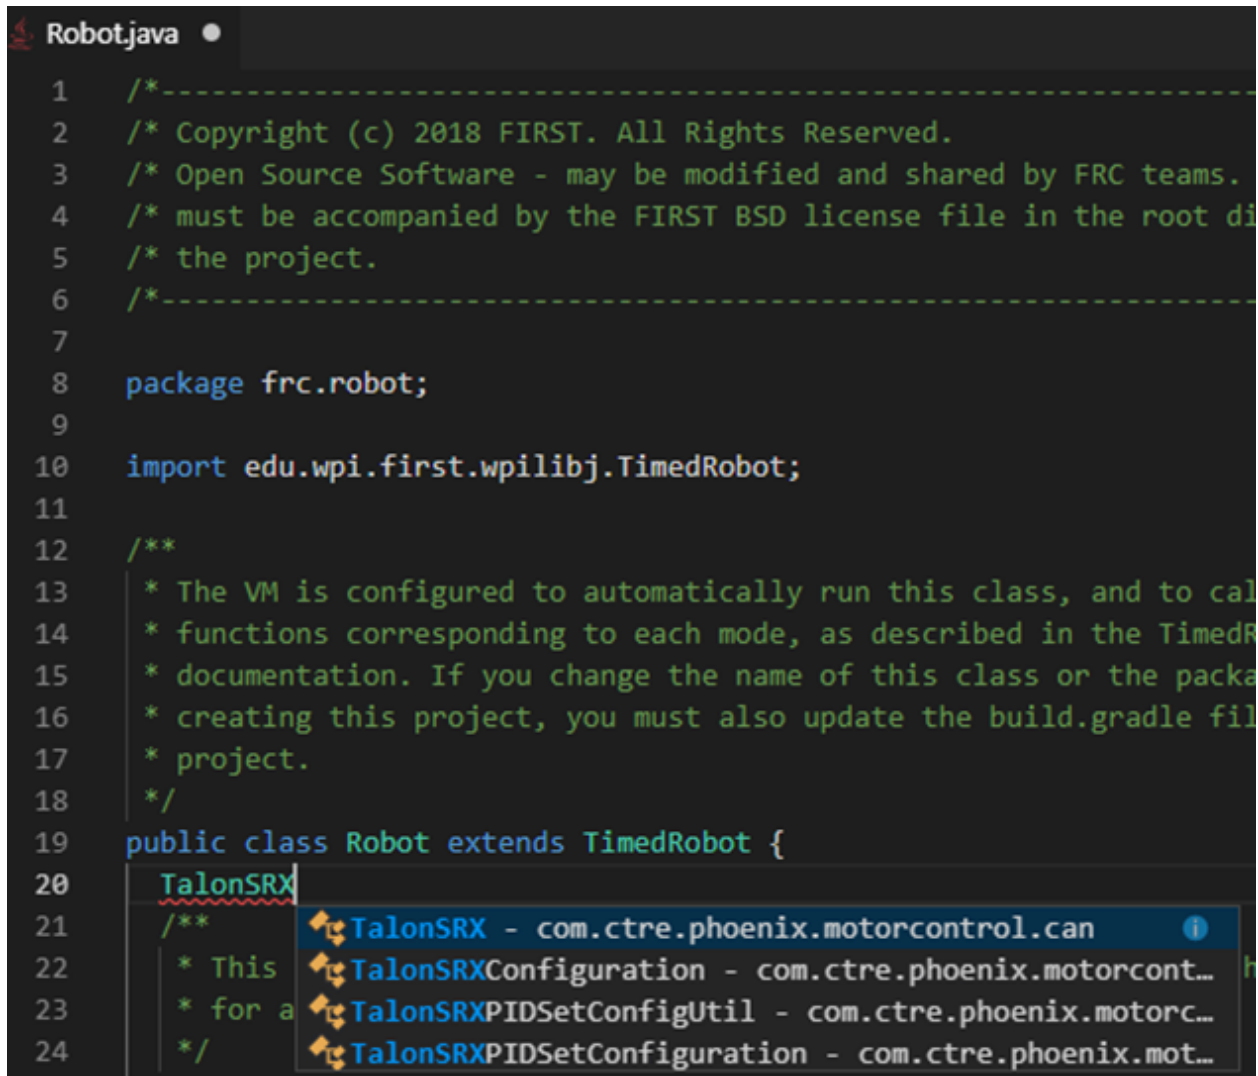

Depending on the version of VS Code used, you may encounter an IntelliSense warning. These can be ignored.

2.6.4 FRC Java Build Test: Single Talon

Create a TalonSRX object. The number specified is the Talon's device ID, however for this test, the device ID is irrelevant.

Typically, you can type "TalonSRX" and watch the intellisense auto pop up. If you press ENTER to select the entry, the IDE may auto insert the import line for you.

```

1  /*-----
2  /* Copyright (c) 2018 FIRST. All Rights Reserved.
3  /* Open Source Software - may be modified and shared by FRC teams.
4  /* must be accompanied by the FIRST BSD license file in the root di
5  /* the project.
6  /*-----
7
8  package frc.robot;
9
10 import edu.wpi.first.wpilibj.TimedRobot;
11
12 /**
13  * The VM is configured to automatically run this class, and to cal
14  * functions corresponding to each mode, as described in the TimedR
15  * documentation. If you change the name of this class or the packa
16  * creating this project, you must also update the build.gradle fil
17  * project.
18  */
19 public class Robot extends TimedRobot {
20     TalonSRX
21     /**
22      * This
23      * for a
24      */

```

Intellisense suggestions for `TalonSRX`:

- TalonSRX - com.ctre.phoenix.motorcontrol.can
- TalonSRXConfiguration - com.ctre.phoenix.motorcont...
- TalonSRXPIDSetConfigUtil - com.ctre.phoenix.motorc...
- TalonSRXPIDSetConfiguration - com.ctre.phoenix.mot...

Add an example call, take your time to ensure to spell it correctly. Use the intellisense features if available.

Here is the final result.

```
Robot.java ●
1  /*-----
2  /* Copyright (c) 2018 FIRST. All Rights Reserved.
3  /* Open Source Software - may be modified and shared by FRC
4  /* must be accompanied by the FIRST BSD license file in the
5  /* the project.
6  /*-----
7
8  package frc.robot;
9
10 import com.ctre.phoenix.motorcontrol.ControlMode;
11 import com.ctre.phoenix.motorcontrol.can.TalonSRX;
12
13 import edu.wpi.first.wpilibj.TimedRobot;
14
15 /**
16  * The VM is configured to automatically run this class, and
17  * functions corresponding to each mode, as described in the
18  * documentation. If you change the name of this class or the
19  * package, you must also update the build.gradle file to
20  * reflect these changes.
21  */
22 public class Robot extends TimedRobot {
23     TalonSRX mytalon = new TalonSRX(0);
24     /**
25      * This function is run when the robot is first started up
26      * for any initialization code.
27      */
28     @Override
29     public void robotInit() {
30         mytalon.set(ControlMode.PercentOutput, 0);
31     }
32 }
```

If you see build errors, carefully find the first erroneous line in the TERMINAL output. Typically, you can CNTRL + click the error line and auto-navigate to the source.

```

22 public class Robot extends TimedRobot {
23     TalonSRX mytalon = new TalonSSRX(0);
24     /**
25      * This function is run when the robot is first started up and should be used
26      * for any initialization code.
27      */
28     @Override

```

2.6.5 FRC C++/Java - Updating Phoenix

If you already have a previous version of Phoenix installed and you want to update to a newer version, follow these steps. Install the latest version of Phoenix on your PC. Basically, rerun the latest installer (same as section above).

Open your robot program in VS Code.

At the top of your screen, a menu will appear. Select “Check for updates (offline)”.

Tip: Alternatively you can use “Check for updates (online)”. However this is **not recommended** as this requires a live Internet connection to use your FRC project.

The menu will now display a list of vendor libraries you can update. Check “CTRE Phoenix”, then click “OK”

2.6.6 FRC C++/Java - Test Deploy

Create a Talon SRX (or Pigeon, CANifier, Victor SPX) and attempt to “deploy”. Adding a print statement also helps to confirm you are actually deploying the software displayed in VsCode. Confirm that the software deployed using DriverStation. DS may report firmware-too-old / not-retrieved errors since the hardware has not been setup yet.

2.7 FRC: Prepare NI roboRIO

2.7.1 Why prepare Robot Controller?

In the previous 2019 season, preparing the Robot Controller typically meant:

1. Installing the Phoenix Diagnostics
2. Installing the Phoenix API into roboRIO (if using LabVIEW).

In the 2020 release of Phoenix, both of these are automatically handled by the library deployment features of WPI Visual Studio Code extensions (C++/Java) and NI LabVIEW.

Phoenix Diagnostics has become a library that is compiled into the FRC robot application. This is a result of the roboRIO CAN bus changes implemented by the NI for 2020. Tuner now communicates with “Phoenix Diagnostic Server” running in the deployed application via an HTTP API.

If the roboRIO does not have a deployed application, a temporary Diagnostic Server application can be deployed from Tuner. This is particularly useful during hardware-bringup.

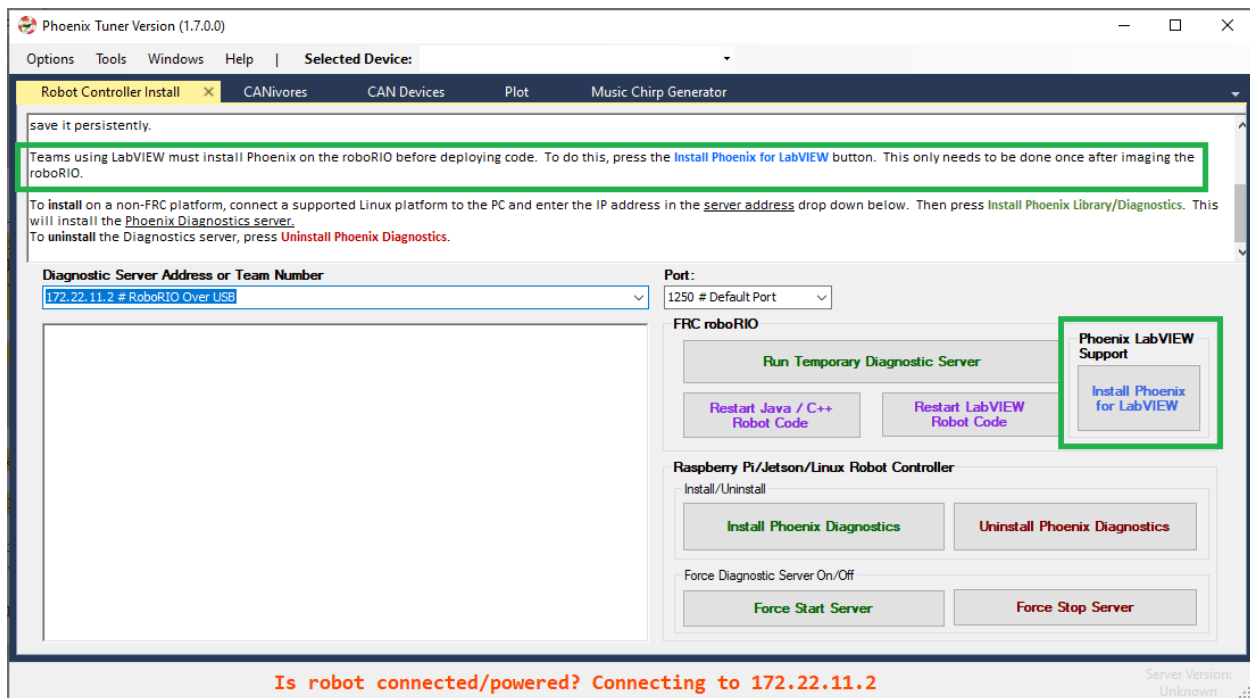

LabVIEW

In the past few seasons, we have relied on a NI LabVIEW feature that would automatically deploy the Phoenix API libraries to the roboRIO. However, we have found circumstances where the NI feature potentially corrupts our libraries during install.

So we have **opted to deploy our binaries directly from Phoenix Tuner** to ensure proper installation.

As a result starting in 2022, LabVIEW users must install Phoenix API libraries into their roboRIO (after roboRIO is imaged). Afterwards deploy your LabVIEW application as you would normally.

Tip: Remember to specify the **Team Number** or **Address** of the roboRIO under Diagnostic Server Address. We recommend using the USB cable and selecting “172.22.11.2” to avoid networking issues.

2.7.2 How to prepare Robot Controller

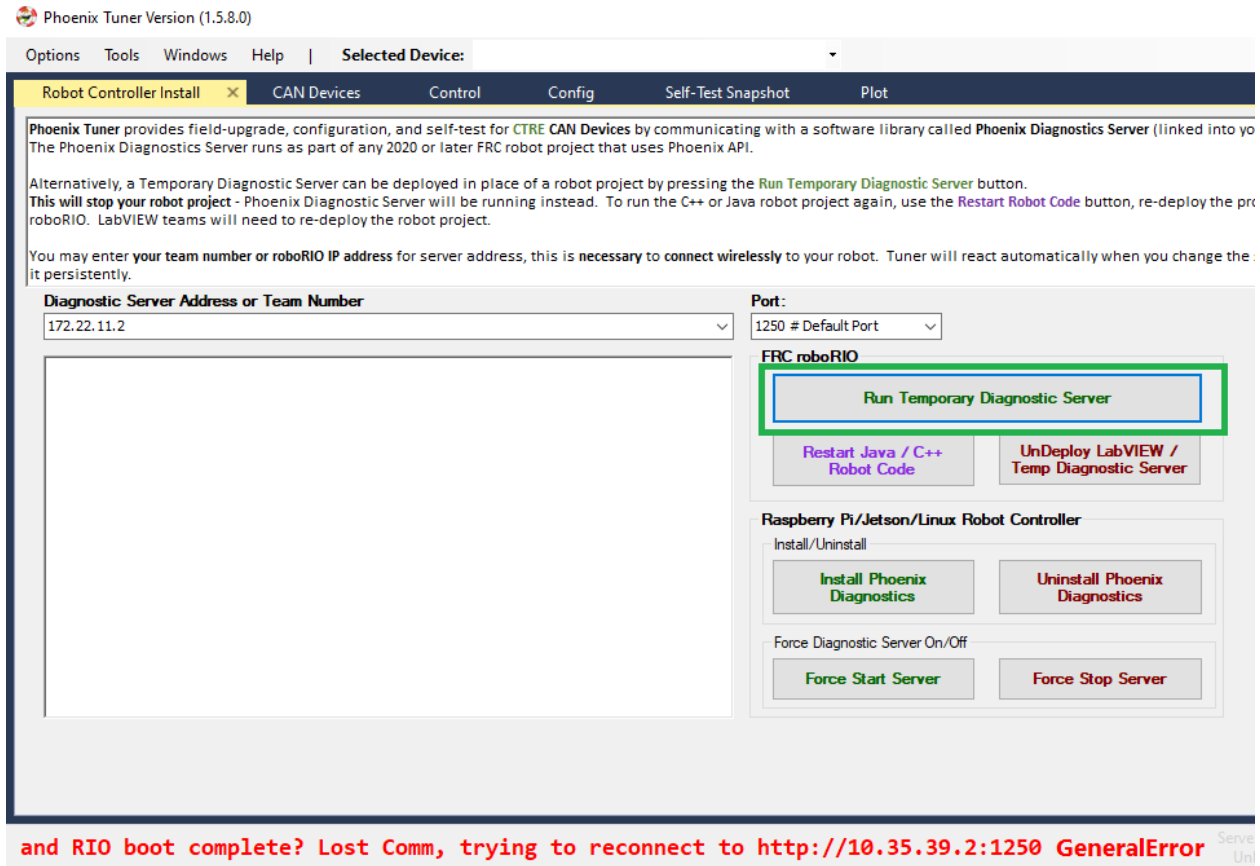

Open Tuner and connect USB between the workstation and the roboRIO.

Select **172.22.11.2 # RoboRIO Over USB** and **1250** for the **address** and **port**. These are generally selected by default, and typically do not require modification.

Deploy the Temporary Diagnostic Server.

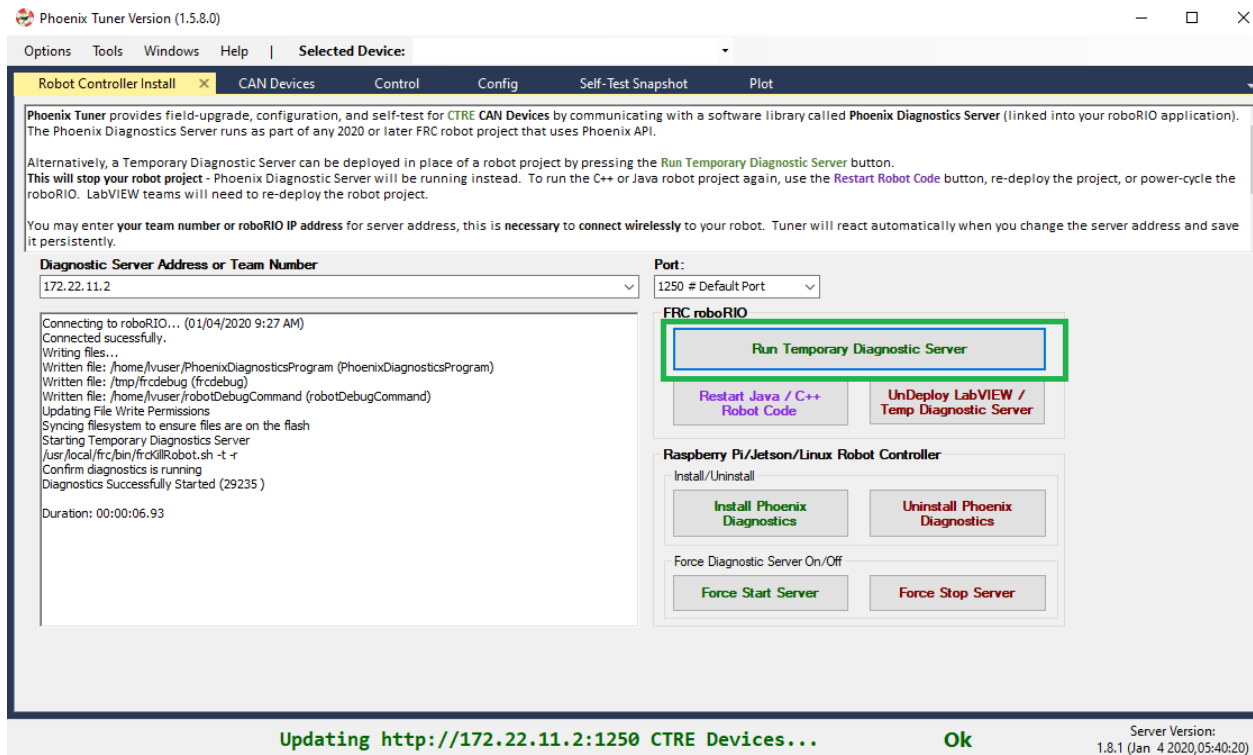

Note: This is unnecessary if a robot application has been deployed already (C++, Java, or LabVIEW).

2.7.3 Verify the robot controller - Tuner

After application deployment, Tuner will immediately connect to the roboRIO.

Confirm the bottom status bar is green and healthy, and server version is present.

If there are CAN device present, they will appear. However, it is possible that devices are missing, this will be resolved in the next major section (CAN Bus bring up).

roboRIO Connection (Wi-Fi/Ethernet)

The recommended connection method for control/plotter features is over **USB or using static IP (Ethernet/Wi-Fi)**. The mDNS strategy used by the roboRIO can *sometimes* fail intermittently which can cause hiccups when submitting HTTP requests to the roboRIO.

Testing has shown that using USB (172.22.11.2) or using static IP address has yielded a greater user experience than the roboRIO-team-frc.local host name has.

Note: Future releases may have improvements to circumvent the limitations of mDNS.

2.7.4 Verify the robot controller - LabVIEW

Create a pristine LabVIEW application. Add a CTRE device to Begin.Vi. For example, create a Talon SRX object, even if the device is not physically present.

Warning: LabVIEW teams not using latest Phoenix may need to chain Phoenix Open VIs together. See the errata here: [LabVIEW Phoenix Open VIs must be chained to guarantee sequential execution](#)

Tip: Drag drop the following into your Begin.vi

Connect DS and turn on Warnings and Prints by selecting the bottom most option.

Upload the application to the robot controller and check the driver station message log.

If everything is working, the Phoenix Initialization message can be found.

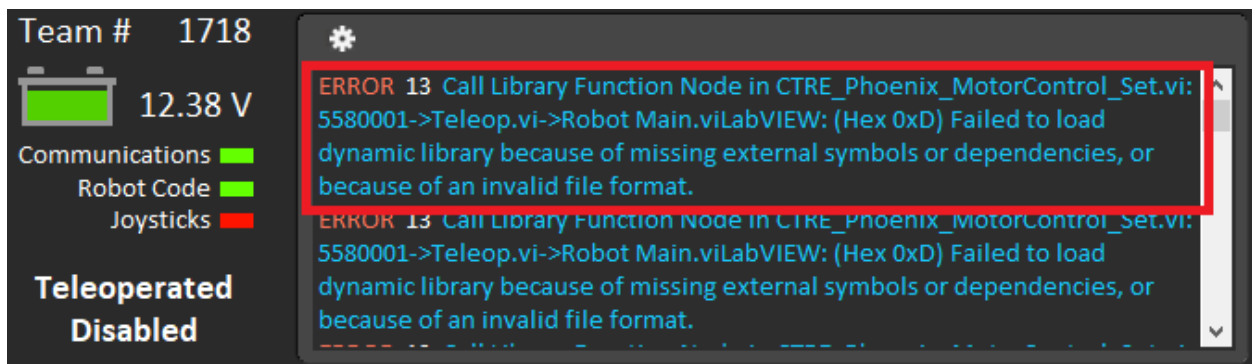

Note: This message will not appear after subsequent “soft” deploy (LabVIEW RAM-only temporary deploys).

If Phoenix API has not been installed into the robot controller, this message will appear.

If you have used Phoenix LifeBoat (which should NOT be used), this message will appear. If this occurs you will need to re-image your roboRIO and then re-follow the instructions in this section exactly, without using LifeBoat.

2.7.5 Verify the robot controller - Web page

The Silverlight web interface provided in previous seasons is **no longer available**. Moving forward, the NI web interface will likely be much simpler.

As a result, **Phoenix Tuner** may embed a *small message reminder indicating that CAN features have been moved to Tuner*. This will depend on the version of Phoenix.

Typically, the message will disappear after 5 seconds. This will not interfere with normal web page features (IP Config, etc.).

172.22.11.2: System Configuration

Save CAN Bus features have been moved to **Phoenix Tuner 4**

Settings

Hostname	NI-roboRIO-030498A1
IP Address	10.2.17.2 (Ethernet) 172.22.11.2 (Ethernet)
DNS Name	NI-roboRIO-030498A1-2.local
Vendor	National Instruments
Model	roboRIO
Serial Number	030498A1
Firmware Version	6.0.0f1
Operating System	NI Linux Real-Time ARMv7-A 4.9.47-rt37-ni-6.0.0f1
Status	Running
System Start Time	Sat Dec 22 2018 18:56:48 GMT-0500 (Eastern Standard Time)
Image Title	roboRIO Image
Image Version	FRC_roboRIO_2019_v9
Comments	asdf
Locale	English
VISA Resource Name	system

Update Firmware

Warning: The roboRIO Web-page does not provide CAN bus support any more as this has been removed by NI. Use Phoenix Tuner instead.

Warning: The roboRIO Web-page does not render correctly if using Internet Explorer (see below). Recommended browsers are Chrome or Firefox.

2.7.6 Verify the robot controller - HTTP API

Tuner leverages the HTTP API provided by Phoenix Diagnostics Server.

So technically you have already confirmed this is working.

But, it is worth noting that this HTTP API can potentially be used by third-party software, or even the robot application itself.

Here is a simple get version command and response.

```
http://172.22.11.2:1250/?action=getversion
```

Here is a simple getdevices command and response.

```

2.8 Prepare Linux Robot Controller

2.8.1 Why prepare Linux Robot Controller?

Preparing a Linux robot controller allows CAN Device control without a roboRIO for non-FRC use or as a secondary processor that can also directly control CAN Devices while still using the roboRIO for Enable/Disable Signal.

Phoenix Diagnostic Server is necessary for Phoenix Tuner to interact with CTRE CAN Devices. Tuner communicates with “Phoenix Diagnostic Server”, a Linux application that provides an HTTP API.

2.8.2 Supported Linux Controllers

Below are the currently supported Linux hardware platforms. An additional SocketCAN device is necessary to utilize the provided software as-is, otherwise a custom platform library is required.

- NVIDIA Jetson TX2
- NVIDIA Jetson Nano
- Raspberry Pi 3
- Raspberry Pi 4

It is possible to use other hardware platforms, however hardware and software setup may be different than this documentation.

Note: CTRE now supports using the *CANivore* as a SocketCAN device with Phoenix CAN FD devices on supported Linux platforms.

Note: CTRE currently recommends the CANable for use as a generic CAN 2.0 SocketCAN device. More information can be found here: <https://canable.io/>

2.8.3 How to prepare Hardware?

Jetson TX2

Follow the documentation provided by NVIDIA to setup the Jetson TX2: <https://developer.nvidia.com/embedded/downloads>

Raspberry Pi/Jetson Nano

Image your device with the respective image below. Other Images can also be used, although these images have been tested and are known to be supported.

Raspbian Buster Image for Raspberry Pi: [Pi Image](#)

Jetson Nano Developer Kit SD Card Image: [Nano Image](#)

Etcher (available [here](#)) is the recommended tool for flashing the image to an SD card. With Etcher open, select your downloaded image and the SD card target, then click “Flash!”.

Once flashed insert the SD card into your device, set up a user and connect to a Wi-Fi network.

CANable (SocketCAN Device)

Once your controller is ready, it is necessary to setup your SocketCAN device.

To use CANable as a SocketCAN device, update the Canable firmware to “candlelight” [using these instructions](#).

Alternatively you can deploy SocketCAN firmware to a HERO. See our repository [on Github](#).

2.8.4 How to prepare Robot Controller Software?

It is recommended to update your Linux platform software before installing the components necessary for Phoenix.

- `sudo apt-get update`
- `sudo apt-get upgrade`

Next, install the required software packages using the following commands:

- CAN Tools `sudo apt-get install can-utils`
- Git `sudo apt-get install git`
- cmake (for build support) `sudo apt-get install cmake`
- libSDL2 (for gamepad support) `sudo apt-get install libSDL2-dev`

With the necessary software installed, clone the example repository into the user directory. This example is a basic C++ project that includes all necessary Phoenix libraries and will be used to validate the hardware and software setup.

From the user directory, run: `git clone https://github.com/CrossTheRoadElec/Phoenix-Linux-SocketCAN-Example.git`

Then navigate into the repo directory: `cd ./Phoenix-Linux-SocketCAN-Example/`.

To ensure the scripts from our cloned repository can be executed, make sure to enable execution privileges.

- `chmod +x build.sh`
- `chmod +x clean.sh`
- `chmod +x canableStart.sh`

Now we can initialize our SocketCAN interface. Bring up the interface as socket “can0” by running the CANable start script: `./canableStart.sh`

Note: if you see the message `Device or resource busy` it means the CAN network is already up and requires no further action.

Configure SocketCAN to allow hot swapping

This is necessary to be able to disconnect and reconnect your USB to CAN adapter without running bringing up the CAN network each time your usb to can adapter is reconnected. Open a new terminal and type `cd /etc/network/..`. Once inside the network directory type `sudo gedit interfaces`.

On Raspberry PI type `sudo gedit interfaces` to edit the file.

A text editor should open. Add the following lines to the file:

```
allow-hotplug can0
iface can0 can static
bitrate 1000000
txqueuelen 1000
up /sbin/ip link set $IFACE down
up /sbin/ip link set $IFACE up type can
```

2.8.5 How to validate SocketCAN functionality?

Make sure you have at least one CTRE CAN device connected for validation of the CAN network. With no CAN traffic, device LEDs will be blinking RED.

Use the `ifconfig` command to list network interfaces, where you can see the status of the CAN socket. The interfaces list should contain an entry for “can0” and should look like this:

```
ctre@ctre:~$ ifconfig
can0: flags=193<UP, RUNNING, NOARP> mtu 16
    unspec 00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00 txqueuelen 1000 (UNSPEC)
    RX packets 45069 bytes 354800 (354.8 KB)
    RX errors 0 dropped 5 overruns 0 frame 0
    TX packets 1562 bytes 8580 (8.5 KB)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0
```

Type `cansend can0 999#DEADBEEF` to send a test CAN frame. Your CAN devices should now blink orange since a valid CAN message has been seen.

Use `candump can0` to see all incoming CAN traffic, which should display all periodic information being sent by a CAN Device. You should see a constant stream of messages similar to this:

```
can0 020401C0 [8] 00 00 00 C0 00 C0 00 00
```

2.8.6 Running the SocketCan Example

Build the example with `./build.sh`.

Then run the example with `./bin/example`.

You're now running Phoenix on your Linux device. Confirm there are no error messages being sent to console output.

Note: You may see error messages if your CAN devices are not yet configured and firmware updated. Follow the [Bring Up: CAN](#) section to setup your CAN devices.

Warning: If your CTRE CAN devices were previously used with a roboRIO it is likely they are FRC locked and will not enable without a roboRIO on the CAN bus. See [Confirm FRC Unlock](#) for instructions to confirm FRC unlock.

You can stop your Program with `Ctrl+C`.

2.8.7 Modifying the SocketCan Example

To modify the example Open the file explorer and navigate to the Phoenix-Linux-SocketCAN-Example folder.

The example is a simple program, so all of the code is contained within `example.cpp`. Edit this file to modify the program.

After modifying the file click the Save button in the top right corner then Go back to [Running the SocketCAN Example](#) to run your modified example.

```

example.cpp (~Phoenix-Linux-SocketCAN-Example) - gedit
example.cpp
~/Phoenix-Linux-SocketCAN-Example

#define Phoenix_No_WPI // remove WPI dependencies
#include "ctre/Phoenix.h"
#include "ctre/phoenix/platform/Platform.h"
#include "ctre/phoenix/unmanaged/Unmanaged.h"
#include <string>
#include <iostream>
#include <chrono>
#include <thread>
#include <SDL2/SDL.h>
#include <unistd.h>

using namespace ctre::phoenix;
using namespace ctre::phoenix::platform;
using namespace ctre::phoenix::motorcontrol;
using namespace ctre::phoenix::motorcontrol::can;

/* make some talons for drive train */
TalonSRX talLeft(1);
TalonSRX talRight(0);

void initDrive()
{
    /* both talons should blink green when driving forward */
    talRight.SetInverted(true);
}

void drive(double fwd, double turn)
{
    double left = fwd - turn;
    double right = fwd + turn; /* positive turn means turn robot LEFT */

    talLeft.Set(ControlMode::PercentOutput, left);
    talRight.Set(ControlMode::PercentOutput, right);
}

/** simple wrapper for code cleanup */
void sleepApp(int ms)
{
    std::this_thread::sleep_for(std::chrono::milliseconds(ms));
}

int main() {
    /* don't bother prompting, just use can0 */
    //std::cout << "Please input the name of your can interface: ";
    std::string interface;
    //std::cin >> interface;
    interface = "can0";
    ctre::phoenix::platform::can::SetCANInterface(interface.c_str());

    /* setup drive */
    initDrive();

    while (true) {
        /* we are looking for gamepad (first time or after disconnect),
        neutral drive until gamepad (re)connected. */
        drive(0, 0);

        // wait for gamepad
        printf("Waiting for gamepad...\n");
        while (true) {
            /* SDL seems somewhat fragile, shut it down and bring it up */
            SDL_Quit();
            SDL_Init(SDL_INIT_JOYSTICK);

            /* poll for gamepad */
            int res = SDL_NumJoysticks();
            if (res > 0) { break; }
            if (res < 0) { printf("Err = %i\n", res); }

            /* yield for a bit */
            sleepApp(20);
        }
        printf("Waiting for gamepad...Found one\n");

        // Open the joystick for reading and store its handle in the joy variable
        SDL_Joystick *joy = SDL_JoystickOpen(0);
        if (joy == NULL) {
            /* back to top of while loop */
            continue;
        }

        // Get information about the joystick
        const char *name = SDL_JoystickName(joy);
        const int num_axes = SDL_JoystickNumAxes(joy);
        const int num_buttons = SDL_JoystickNumButtons(joy);
        const int num_hats = SDL_JoystickNumHats(joy);
        printf("Now reading from joystick '%s' with:\n"
            "%d axes\n"
            "%d buttons\n"
            "%d hats\n\n",
            name,
            num_axes,
            num_buttons,
            num_hats);
    }
}

```

C++ Tab Width: 8 Ln 39, Col 2 INS

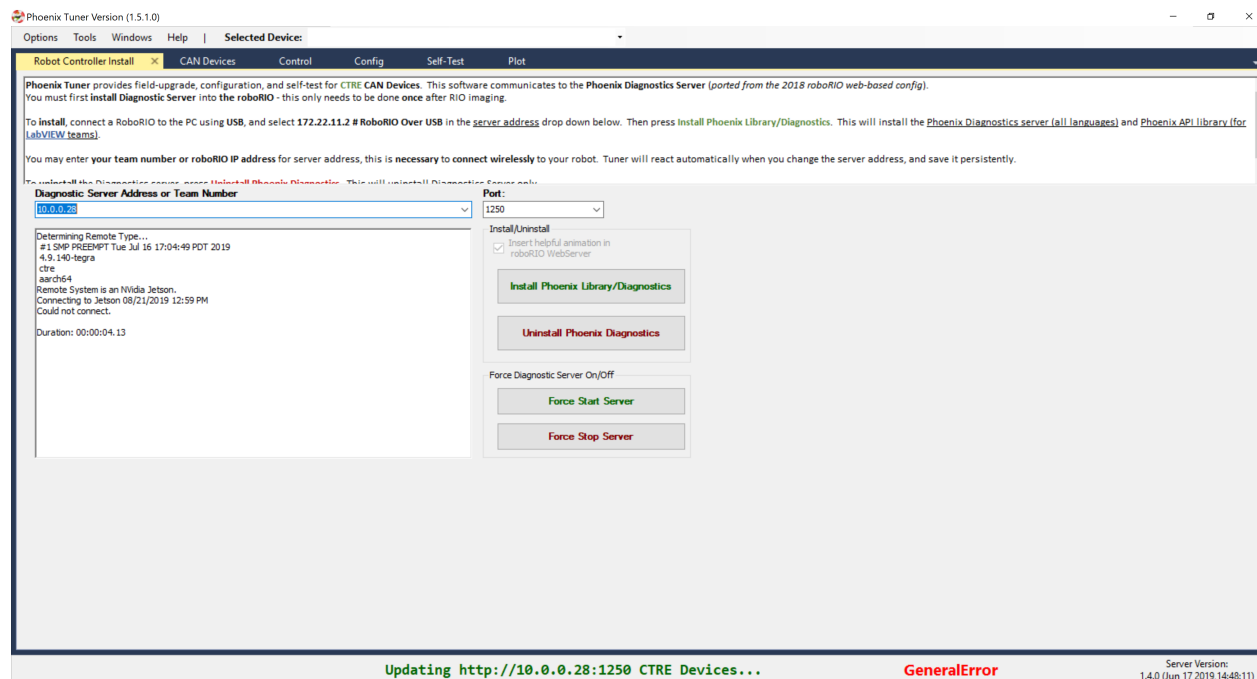

2.8.8 How to setup Phoenix Tuner?

With the CAN network up and running, Phoenix Tuner can be used with the Linux Robot Controller in the same manner as the roboRIO.

Note: SSH must be enabled on the Linux Robot Controller to perform a field upgrade or modify a device's configuration using Phoenix Tuner.

Connect both the Linux Robot Controller and Windows machine to the same network via WiFi or an ethernet connection.

Enter the IP Address or Name of the Linux Robot Controller into Phoenix tuner.

Tip: To find the IP address in Linux, run the `ifconfig` command to display network interfaces. The IP address will be listed under a 'lan' or 'wlan' entry and listed as inet.

```
wlan0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
    inet 10.0.0.28 netmask 255.255.255.0 broadcast 10.0.0.255
    inet6 fe80::8a95:2aa9:50d5:37a7 prefixlen 64 scopeid 0x20<link>
    ether 74:da:38:f9:02:1a txqueuelen 1000 (Ethernet)
    RX packets 10676 bytes 1114331 (1.1 MB)
    RX errors 0 dropped 0 overruns 0 frame 0
    TX packets 11573 bytes 14310767 (14.3 MB)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0
```

Setting up the Phoenix Diagnostics Server

The Phoenix Diagnostics Server is an HTTP server that communicates with the Phoenix Tuner. There are two versions of the server: a standalone version installed through Phoenix Tuner (legacy), and a version built into your user program (latest). Only one version of the diagnostics server may be running at any given time. We recommend you run the diagnostics server through your user program.

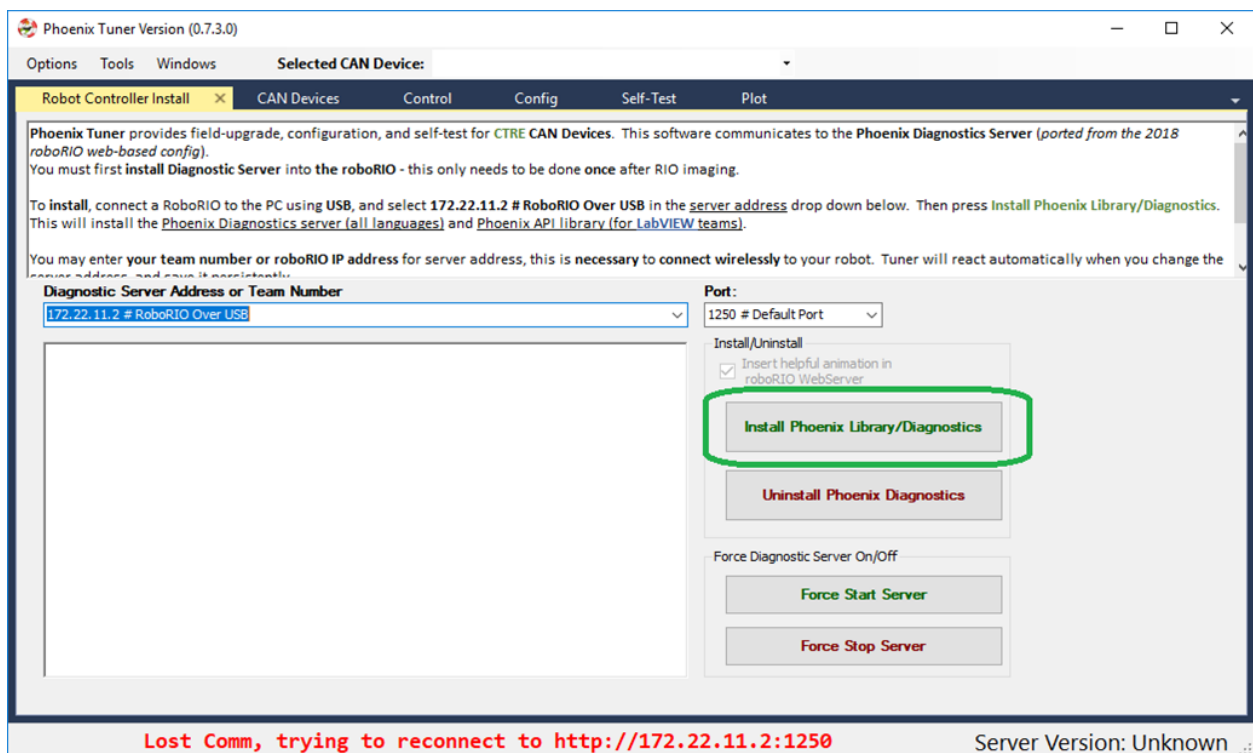

You can disable the diagnostics server in your program by adding `c_SetPhoenixDiagnosticsStartTime(-1);` to the start of your main method. The line is commented out in the example program.

Warning: The instructions below are available for legacy support. We recommend you instead run the Phoenix Diagnostics Server in your user program.

Warning: The legacy instructions below currently do not work. See: <https://github.com/CrossTheRoadElec/Phoenix-Linux-SocketCAN-Example/issues/15>

To install the standalone diagnostics server:

Press the Install button.

Enter your username and password when prompted.

Note: The user must have sudo permissions to successfully install.

Note: To find your username look at the text before the @ in the terminal. For example, in this terminal the user is ctre.

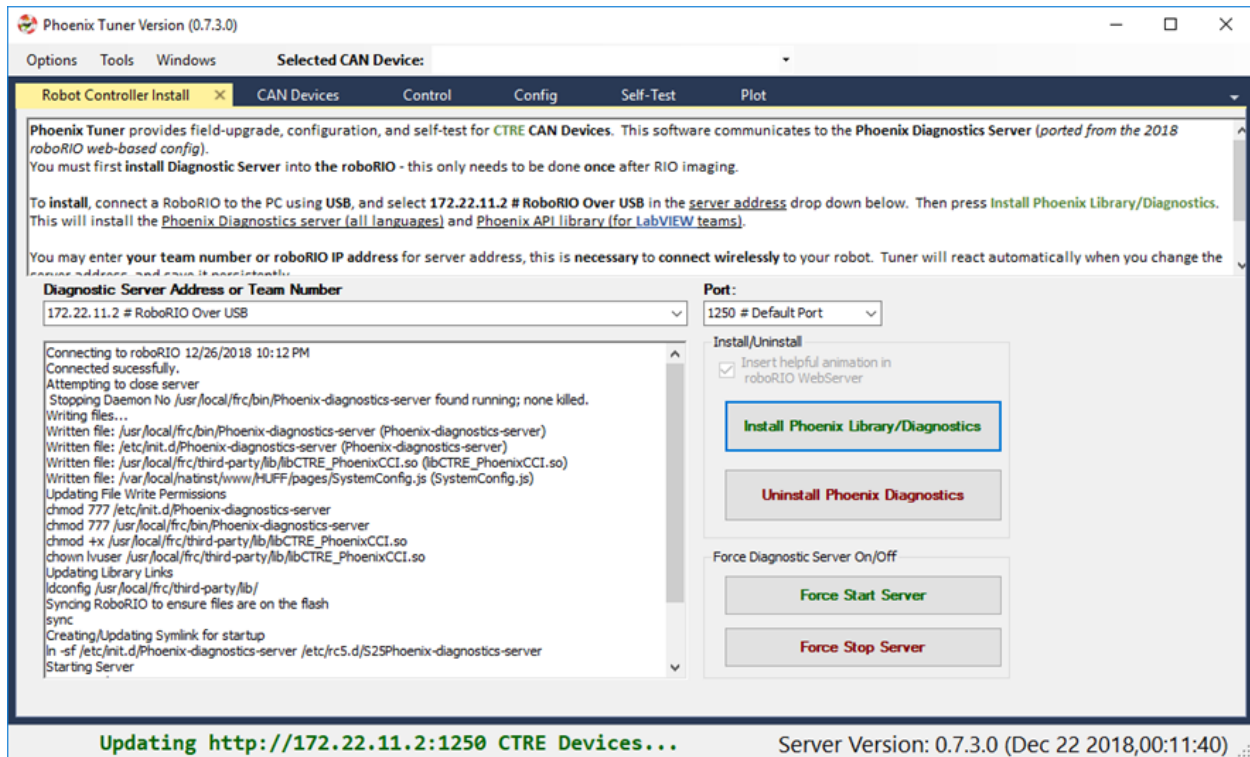

Tuner will then install and start the diagnostics server on the device.
The diagnostics server is now installed and running on your device.

2.8.9 Verify the robot controller - Tuner

After installation is complete, Tuner will immediately connect to your device.

Confirm the bottom status bar is green and healthy, and server version is present. If this is not the case and you are using the standalone server (legacy), you may need to re-start the Diagnostic Server by using the “Force Stop Server” and “Force Start Server” buttons.

If there are CAN device present they will appear in the “CAN Devices” tab. However, it is possible that devices will appear to be missing - this will be resolved in “Bring Up: CAN Bus”.

2.9 Initial Hardware Testing

For your competition team to have the best chance of success, hardware components should be tested as soon as they are received. This is generally done by:

- Powering up the device and confirming LED states.
- Ensuring hardware shows up in Tuner if wired to CAN Bus.
- Drive outputs / drive motor in both directions (if motor controller).

This is explained in the sections below, but it is worth pointing out how important this step is. It is in your team's best interest to test ALL purchased robot components immediately and in isolation. Here are the reasons why:

- Robot *replacement* components should be in a **state of readiness**. Otherwise a replacement during competition can yield erroneous behavior.
- Many robot components (in general) have **fixed warranty periods**, and replacements must be done within them.
- Confirming devices are functional **before handing them to students** ensures best chance of success. If a student later damages hardware, they need to understand how they did it to ensure it does not happen again. Without initial validation, you can't determine root-cause.

Much of this is done during the "bring-up" phase of the robot. However, there is much validation a team can do long before the robot takes form.

Unfortunately, there are **many** teams that do not perform this step, and end up isolating devices and re-implementing their cable solutions at competition, because this was not done

during robot bring up.

Note: “Bring up / Board bring up / Hardware bring up” is an engineering colloquial phrase. It is the initial setup and validation phase of your bench or robot setup.

2.10 Bring Up: CAN Bus

Now that all of the software is installed and verified, the next major step is to setup hardware and firmware.

2.10.1 Understand the goal

At this point we want to have reliable communication with CAN devices. There are typically two failure modes that must be resolved:

- There are same-model devices on the bus with the same device ID (devices have a default device ID of '0').
- CAN bus is not wired correctly / robustly.

This is why during hardware validation, you will likely have to isolate each device to assign a unique device ID.

Note: CTRE software has the ability to resolve device ID conflicts without device isolation, and CAN bus is capable of reporting the health of the CAN bus (see Driver Station lightening tab). However, the problem is when **both** root-causes are occurring at the same time, this can confuse students who have no experience with CAN bus systems.

Note: Many teams will preassign and update devices (Talon SRXs for example) long before the robot takes form. This is also a great task for new students who need to start learning the control system (with the appropriate mentor oversight to ensure hardware does not get damaged).

Note: Label the devices appropriately so there is no guessing which device ID is what. Don't have a label maker? Use tape and/or Sharpie (sharpie marks can be removed with alcohol).

Warning: Talon SRX and Talon FX must use unique device IDs for Phoenix API to function correctly. This design decision was made so that teams could use the existing TalonSRX class for control.

2.10.2 Check your wiring

Specific wiring instructions can be found in the user manual of each product, but there are common steps that must be followed for all devices:

- If connectors are used for CANBus, **tug-test each individual crimped wire** one at a time. Bad crimps/connection points are the most common cause of intermittent connection issues.
- Confirm red and black are not flipped. **Motor Controllers typically are not reverse power protected.**
- Confirm battery voltage is adequate (through Driver Station or through voltmeter).
- Manually inspect and confirm that green-connects-to-green and yellow-connects-to-yellow at every connection point. **Flipping/mixing green and yellow is a common failure point during hardware bring up.**
- Confirm breakers are installed in the PDP where appropriate.
- Measure resistance between CANH and CANL when system is not powered (should measure $\sim 60\Omega$). If the measurement is 120Ω , then confirm both RIO and PDP are in circuit, and PDP jumper is in the correct location.

2.10.3 Power up and check LEDs

If you haven't already, power up the platform (robot, bench setup, etc.) and confirm LEDs are illuminated (at all) on all devices.

You may find many of them are blinking or "blipping" red (no communication).

Tip: If you are color-blind or unable to determine color-state, grab another team member to assist you.

Note: If using Ribbon cabled Pigeon IMUs, Pigeon LEDs will reflect the ribbon cable, not the CAN bus. At which point any comm issue with Pigeon will be resolved under section Bring Up: Pigeon IMU.

2.10.4 Open Phoenix Tuner

Navigate to the CAN devices page.

This capture is taken with no devices connected to the roboRIO. roboRIO will take around 30 seconds to boot.

Tip: There is a modernized version called [Tuner X](#) that is available for Windows and Android devices (works with Phoenix 5 and [Phoenix Pro](#)).

2.10.5 LEDs are red - now what?

We need to rule out same-id versus bad-bus-wiring. There are two approaches. Approach 1 will help troubleshoot bad wiring and common IDs. Approach 2 will only be effective in troubleshooting common IDs. But this method is noteworthy because it is simple/quick (no wiring changes, just pull breakers).

The specific instructions for changing device ID are in the next section. Review this if needed.

Approach 1 (best)

Procedure:

- **Physically connect CAN bus from roboRIO to one device only. Circumvent your wiring if need be.**
- Power boot robot/bench setup.
- Open Phoenix Tuner and wait for connection (roboRIO may take ~30 seconds to boot)
- Open CAN devices tab
- Confirm if CAN device appears.
- Use Tuner to change the device ID
- Label the new ID on the physical device
- Repeat this procedure for every device, one at a time.

If you find a particular device where communication is not possible, scrutinize device's power and CAN connection to roboRIO. Make the test setup so simple that the only failure mode possible is within the device itself.

Note: Typically, there must be two termination resistors at each end of the bus. One is in the RIO and one is in the PDP. But during bring-up, if you keep your harness short (such as the CAN pigtail leads from a single Talon) then the internal resistor in the RIO is adequate.

Approach 2 (easier)

Procedure:

- **Leave CAN bus wiring as is.**
- **Pull breakers and PCM fuse from PDP.**
- **Disconnect CAN bus pigtail from PDP.**
- **Pick the first device to power up and restore breaker/fuse/pigtail so that only this CAN device is powered.**
- Power boot robot/bench setup.
- Open Phoenix Tuner and wait for connection (roboRIO may take ~30 seconds to boot)
- Open CAN devices tab
- Confirm if CAN device appears. If device does not appear, scrutinize device's power and CAN connection to roboRIO.
- Use Tuner to change the device ID
- Label the new ID on the physical device
- Repeat this procedure for every device.

If you find a particular device or section of devices where communication is not possible, then the CAN bus wiring needs to be re-inspected. Remember to “flick” / “shake” / “jostle” the CAN wiring in various sections to attempt to reproduce red LED blips. This is a sure sign of loose contact points.

If you are able to detect and change device ID on your devices individually, begin piecing your CAN bus together. Start with roboRIO <—> device <—> PDP, to ensure termination exists at both ends. Then introduce the remaining devices until a failure is observed or until all devices are in-circuit.

If introducing a new device creates a failure symptom, scrutinize that device by replacing it, inspecting common wires, and inspecting power.

Note: If 2014 PDP is the only device that does not appear or has red LEDs, see PDP boot up section for specific failure mode.

Note: If ribbon cable Pigeon does not appear, it likely is because Talon has old firmware.

At the end of this section, all devices should appear (notwithstanding the above notes) and device LEDs should not be red. PCM, Talon, Victor, Pigeon, and CANifier typically blink orange when they are healthy and not controlled. PDP may be orange or green depending on its sticky faults.

2.10.6 Set Device IDs

Note: A CTRE device can have an ID from 0 to 62. If you select an invalid ID, you will generally get an immediate prompt.

Below we see several devices, however the physical robot has 19 actual devices. Because all the Talons have a device ID of '0', they do not show up as unique hardware. This must be resolved before you can attempt utilizing them.

Phoenix Tuner Version (0.7.3.0)

Selected CAN Device:									
Robot Controller Install		CAN Devices	Control	Config	Self-Test	Plot			
Devices (Count:6)	Software Status	Hardware	ID	Fi...	Manufactur...	B...	H..	Vendor	
Omar's CANifier	Running Application.	CANifier	00	0.42	Sept 3, 2017	1.0	1.0	Cross The Road Electronics	
PCM (Device ID 0)	Running Application.	PCM	00	1.62	June 17, 2015	3.0	1.6	Cross The Road Electronics	
PDP (Device ID 0)	Running Application.	PDP	00	1.30	Aug 14, 2014	3.0	1.1	Cross The Road Electronics	
Pigeon (Device ID 0)	Running Application.	Pigeon	00	0.41	Nov 9, 2016	1.0	1.1	Cross The Road Electronics	
Talon SRX (Device ID 0)	There are 14 devices with this Device ID. Running Application.	Talon SRX	00	3.9	Aug 14, 2015	3.2	1.7	Cross The Road Electronics	
Victor 0 - Left	Running Application.	Victor SPX	00	3.9	Nov 19, 2017	0.2	1.0	VEX Robotics	

Note: We recommend isolating each device and assigning a unique ID first. But in the event there is a conflict, expect an entry mentioning multiple devices. When selecting a device, the actually physical device selected will be the conflict-id device that booted last. You can use this information to control which Talon you are resolving by power cycling the conflict device, then changing its ID in Tuner.

Select the device and use the numeric entry to change the ID. Note the text will change blue when you do this. Then press "Change ID" to apply the changes.

If operation completes, an OK will appear in the bottom status bar (this is true of all operations). Also note the ID has updated in the device list, and the ID text is now black again.

Tip: All production CTRE hardware ships with a default ID of '0'. As a result, it is useful to start your devices at device ID '1', so you can cleanly add another out-of-box device without introducing a conflict.

When complete, make sure every device is visible in the view. Use the Blink button on each device to confirm the ID matches the expected physical device.

Note: The device count is present in the top left corner of the device list. Use this to quickly confirm all devices are present.

Note: If ribbon-cabled pigeon is not present, then the host talon likely has old firmware.

2.10.7 Field upgrade devices

At this point all devices are present, but the firmware is likely old.

The 2020 season has 20.X firmware for Talon FX, Talon SRX, Victor SPX, CANCoder, CANifier, and Pigeon IMU. Moving forward, the first number of the version will represent the season (next year's 2021 firmware will be 21.X).

20.X firmware is required for all motor controllers and CANCoder. 20.X is also recommended for CANifier and Pigeon IMU.

Note: Latest PDP is 1.40. PDP typically ship with 1.30. 1.40 has all of the signals read by the WPILib software, and will tare the current measures so current will read 0 instead of ~1-2 amps when there is no current-draw. Updating to 1.40 is recommended.

Note: Latest PCM is 1.65. PCM typically ship with 1.62. Firmware 1.65 has an improvement where hardware-revision 1.6 PCMs will not-interrupt compressor when blacklisting a shorted solenoid channel. Older revisions will pause the compressor in order to safely sticky-fault,

new revisions have no need to do this (if firmware is up to date).

Select the CRF under the Field-upgrade section then press Update Device. The CRFs are available in multiple places, and likely are already on your PC. See section *Device Firmware Files (crf)*.

If there are multiple devices of same type (multiple Talon SRXs for example), you may check Update all devices. This will automatically iterate through all the devices of the same type, and update them. If a device field-upgrade fails, then the operation will complete. Confirm Firmware Version column in the device list after field-upgrade.

Note: Each device takes approximately 15 seconds to field-upgrade.

When complete every device should have latest firmware.

2.10.8 Pick device names (optional)

The device name can also be changed for certain device types: - CANifier - Pigeon IMU (on CAN bus only) - Talon SRX and Victor SPX

Note: PDP and PCM do not support this.

Note: Ribbon cabled Pigeon IMUs do not support this.

Note: To re-default the custom name, clear the “Name” text entry so it is blank and press “Save”.

2.10.9 Self-test Snapshot

At this point every device should be present on the bus, and updated to latest. This is an opportune time to test the Self-test Snapshot feature of each device.

Select each device either in the device list, or using the dropdown at the center-top. This dropdown is convenient as it is accessible regardless of how the tabs are docked with Tuner.

Note: If you press the “Selected CAN device” text next to dropdown, you will be taken back to the CAN Devices tab.

Navigate to the Self-test Snapshot tab. If Self-test Snapshot tab is not present, use the Windows menu bar to reopen it.

Press Self-test Snapshot button and confirm the results.

Note: This Pigeon has not had its firmware updated, this is reported at the top.

You can also use the Blink/Clear faults button to blink the selected device and clear any previously logged sticky faults.

2.10.10 Driver Station Versions Page

It is worth mentioning there is basic support of reporting the CAN devices and their versions in the diagnostics tab of the Driver Station.

If there is a mixed collection of firmware versions for a given product type, the version will report “Inconsistent”.

Note: The recommended method for confirming firmware versions is to use Phoenix Tuner.

Note: There is a known issue where ribbon-cabled Pigeons may erroneously report as a Talon. Since this is not a critical feature of the Driver Station, this should not be problematic for FRC teams.

2.11 Bring Up: CANivore

2.11.1 Supported systems

Currently, the following systems are supported for CANivore development:

- roboRIO
- Windows (x86-64)
- Linux desktop (x86-64)
- Raspberry Pi (ARM 32-bit and 64-bit)
- NVIDIA Jetson

Note: Custom bit rates and CAN 2.0 are not supported at this time. The parameters passed into SocketCAN are not applied by the firmware.

2.11.2 Non-FRC Linux Kernel Module

On non-FRC Linux systems, the canivore-usb kernel module must be installed to add SocketCAN support for the CANivore. The kernel module is distributed through APT. Our deb package repository must be added to your APT sources list prior to the initial installation:

```
sudo curl -s --compressed -o /usr/share/keyrings/ctr-pubkey.gpg "https://deb.ctr-electronics.com/ctr-pubkey.gpg"
sudo curl -s --compressed -o /etc/apt/sources.list.d/ctr2022.list "https://deb.ctr-electronics.com/ctr2022.list"
```

After adding our sources, the kernel module can be installed and updated using the following:

```
sudo apt update
sudo apt install canivore-usb
```

Tip: To get a robot application up and running quickly, check out our [Phoenix SocketCAN Example](#).

2.11.3 View attached CANivores

Open Phoenix Tuner, go to the CANivores tab, and click on the Refresh CANivores button to get a list of CANivores attached to the target system. You can specify the target system in the Robot Controller Install tab.

Note: The Phoenix Diagnostic Server must be running on the target system to use the

CANivores page.

Note: The CANivores tab **does not work on non-FRC Linux systems**. This will be fixed in a future update. As a workaround, you can use the *caniv CLI* to configure your CANivores.

Tip: There is a modernized version called **Tuner X** that is available for Windows and Android devices (works with Phoenix 5 and **Phoenix Pro**).

Tip: If you are connecting to CANivores on your local Windows machine, there is a CANivore-usb option in the Diagnostic Server Address dropdown. This option runs a diagnostic server within Tuner so you do not need to run a robot project to communicate with CANivores.

2.11.4 Field upgrade CANivores

In the CANivores tab of Phoenix Tuner, select the CANivore you wish to update. Select the CRF under the Field-upgrade section then press Update Device. The CRFs are available in multiple places, and likely are already on your PC. See section *Device Firmware Files (crf)*.

If you wish to update all attached CANivores, check Update all CANivores. If a CANivore field-upgrade fails, then the operation will complete. Confirm Firmware Version column in the device list after field-upgrade.

2.11.5 Rename CANivores

CANivores can be given custom names for use within a robot program. Select the CANivore you wish to rename. Under the General CANivore Configuration section, set the new name and click “Change Name”.

Note: CANivore names cannot be longer than 32 characters.

Note: To re-default the custom name, clear the “Name” text entry so it is blank and press “Change Name”.

2.11.6 Configure CAN bus termination

The CANivore has a 120-ohm programmable resistor for terminating the CAN bus. The resistor can be configured using the CAN Bus Termination Enable and Disable buttons in the CANivores tab of Phoenix Tuner. The current state of the terminating resistor can be seen in the "CAN Bus Termination" column of the list of CANivores.

Note: A CAN bus requires two terminating resistors - one at each extreme end. If only one is present, communication over CAN may fail.

2.11.7 Configure ESP32

The CANivore includes an **ESP32 module** which provides the ability to **run custom code**, which in turn allows **access to Wi-Fi and Bluetooth features**. By default, the ESP32 is disabled and held in reset. Users can enable the ESP32 via Phoenix Tuner so that it is allowed to run.

CANivore provides a software USB COM port, which typical ESP32 software tools can use to deploy and debug.

Examples will be coming soon!

The current state of the ESP32 can be seen in the "ESP32 State" column of the list of CANivores.

Tip: For convenience, the software USB COM port is always available and can be used to deploy an ESP32 application even if setting is disabled. However ESP will not boot up after power reset if setting is disabled.

Warning: FRC rules *typically* require that no device is allowed to emit wireless signals during an FRC competition. Teams are encouraged to read the latest game rules and disable ESP32 during competition use if need be.

2.11.8 CANivore API

In the constructors for CANivore-compatible CAN devices, there is an optional string parameter to set the device's CAN bus. This string can be the CANivore's name or serial number. On non-FRC Linux systems, this string can also be a SocketCAN interface.

If no CAN bus string is passed into the constructor, or the CAN bus string is empty:

- On the roboRIO, the system will use the roboRIO native CAN bus.
- On Windows, the system will use the first CANivore found. (Requires Phoenix 5.22+)
- On non-FRC Linux systems, the system will use SocketCAN interface can0.

Note: If there are multiple CANivores with the same name, the system will use the first CANivore found.

Note: You can explicitly specify that a device should use the roboRIO native CAN bus by passing down "rio" or "roborio".

```
TalonFX fx_default = new TalonFX(0); // This constructs a TalonFX on the RIO native_
↳CAN bus
TalonFX fx_rio = new TalonFX(1, "rio"); // This constructs a TalonFX on the RIO_
↳native CAN bus
TalonFX fx_drivebase = new TalonFX(0, "Drivebase"); // This constructs a TalonFX on_
↳the CANivore bus named "Drivebase"
```

(continues on next page)

(continued from previous page)

```
CANCoder cc_elevator = new CANCoder(0, "Elevator"); // This constructs a CANCoder on
↳ the CANivore bus named "Elevator"
```

2.11.9 CANivore Status Prints

When working with CANivore CAN buses in a robot program, Phoenix prints some messages to report the state of the CANivore connection. These messages can be useful to debug connection issues (bad USB vs bad CAN) or report bugs to CTR Electronics.

Table 1: Connection Messages

Message	Connection Status
CANbus Failed to Connect	Could not connect to a CANivore with the given name or serial number
CANbus Connected	Successfully found and connected to the CANivore with the given name or serial number
CANbus Disconnected	Detected that a CANivore USB device has been disconnected

Table 2: CANivore Bring-up Messages (Linux only)

Message	Bring-up Status
CANbus Failed Bring-up	Found and connected to the CANivore, but could not configure the device or start the network
CANbus Successfully Started	Successfully configured the CANivore and started the network

Table 3: Network State Messages

Message	Network State
CANbus Network Down	Linux: The SocketCAN network has been deactivated, USB-to-CAN activity has stopped Windows: Could not open the communication channels for USB-to-CAN traffic
CANbus Network Up	Linux: The SocketCAN network has been activated, USB-to-CAN activity has resumed Windows: Successfully opened the communication channels for USB-to-CAN traffic

2.11.10 caniv - CANivore CLI

caniv is a Command-line Interface (CLI) to interact with CANivores outside of Phoenix Tuner. After running any action on the CANivores page of Phoenix Tuner, Latest caniv is deployed to the target system.

Note: Unlike the CANivores page in Phoenix Tuner, caniv does **not** require a running Phoenix Diagnostic Server.

On Linux systems (including the roboRIO), caniv can be found at /usr/local/bin. On Windows systems, the program is in the Phoenix Tuner install location, under Binary\windows\ctre.

To view a list of available commands, run caniv either with no parameters or with --help.

```
admin@roboRIO-3539-FRC:~# caniv
CTRE CANivore Command-line Interface
Usage:
  caniv [OPTION...]

  -d, --device arg  Selects CANivore by serial number or name. Specify "*" to
                    select any device.
  -a, --any         Equivalent to [-d "*"]
  -v, --verbose     Print verbose messages
  -h, --help        Print this help message

Action options:
  --version         Get version of this program
  -l, --list        List all discovered CANivore devices
  -s, --setup       Brings up the CANivore network
  --termination arg Enables or Disables the CAN bus termination resistor
  --esp32 arg       Enables or Disables the ESP32 module
  -b, --blink       Blinks selected CANivore
  -r, --reset       Resets selected CANivore
  -n, --name arg    Sets name of selected CANivore. You must reset the
                    CANivore for the new name to take effect.
  -f, --flash arg   Field upgrades selected CANivore with crf file
  -i, --info        Solicit information from selected CANivore

admin@roboRIO-3539-FRC:~#
```

2.12.1 Phoenix Tuner Self-test Snapshot

The screenshot shows the Phoenix Tuner software interface. The top menu bar includes Options, Tools, Windows, and Help. Below it, there's a status bar indicating "Selected CAN Device: PCM (Device ID 0)".

CAN Devices:

- Omar's CANifier
- PCM (Device ID 0)
- PDP (Device ID 0)
- Pigeon (Device ID 0)
- Talon 0 - Right
- Talon 1 - Left
- Talon SRX (Device ID 10)
- Talon SRX (Device ID 11)
- Talon SRX (Device ID 12)
- Talon SRX (Device ID 13)
- Talon SRX (Deviio)
- Talon SRX (Devio)
- Talon SRX (Devio)
- Talon SRX (Devio)
- Talon SRX (Devio)
- Talon SRX (Devio)
- Talon SRX (Devio)
- Talon SRX (Devio)
- Talon SRX (Devio)
- Victor 0 - Left

Self-Test Results:

```

PCMS IS NOT ENABLED! If robot is enabled maybe the ID is wrong?
Close-Looping is ON, but PCMS is DISABLED.
Comp Is Off
Pressure is full.

(Fault)      (Now)    (Sticky)
Comp Curr Too High   0         0
Comp Short Circuit    0         0
Solenoid Fuse        0         0
Comp Curr Too Low     0         0
Solen 0              0
Solen 1              0
Solen 2              0
Solen 3              0
Solen 4              0
Solen 5              0
Solen 6              0
Solen 7              0

Solen 0 is OFF
Solen 1 is OFF
Solen 2 is OFF
Solen 3 is OFF
Solen 4 is OFF
Solen 5 is OFF
Solen 6 is OFF
Solen 7 is OFF

Battery (V): 12.19
Solenoid (V): 11.97
Compressor (A): 0.00

"Light Device LED" to clear sticky faults (disables compressor momentarily).

Build:Dec 22 2018 00:05:32
Press "Refresh" to close.
```

At the bottom right, there are two buttons: "Self-Test" and "Blink / Clear Faults".

Create a Solenoid object in LabVIEW/C++/Java and set channel 0 to true.

```
import edu.wpi.first.wpilibj.Solenoid;
public class Robot extends TimedRobot {
    Solenoid _solenoid = new Solenoid(0, 0); // first number is the PCM ID (usually 0), second number is the solenoid channel

    public void teleopPeriodic() {
        _solenoid.set(true);
    }
}
```

Tip: Image below can be dragged/dropped into LabVIEW editor.

Then confirm using the Solenoid LED on the PCM and Self-test Snapshot in Tuner.

Tip: There is a modernized version called **Tuner X** that is available for Windows and Android devices (works with Phoenix 5 and **Phoenix Pro**).

Generally creating a solenoid object is sufficient for the compressor features to function. In order for the compressor output to activate, all of the following conditions must be met:

- The robot is enabled via the Driver Station
- Robot application has created a solenoid (or compressor object) with the correct PCM

device ID.

- PCM must be powered/wired to CAN Bus.
- Pressure-switch reads too-low (can be confirmed in Self-test Snapshot).
- No compressor related faults occur (can be confirmed in Self-test Snapshot)

Tip: Creating a compressor object is not necessary, but can be useful to force the compressor **off despite pressure reading too-low** with the `setClosedLoopControl` routine/VI. This can be useful for robot power management during critical operations.

```
import edu.wpi.first.wpilibj.Compressor;
public class Robot extends TimedRobot {
    Compressor _compressor = new Compressor();

    public void teleopPeriodic() {
        _compressor.setClosedLoopControl(false); //This will force the compressor off
    }
}
```

Tip: Image below can be dragged/dropped into LabVIEW editor.

2.13 Bring Up: PDP

At this point PDP will have firmware 1.40 (latest). Open Phoenix Tuner to confirm. Use Self-test Snapshot to confirm reasonable values for current and voltage.

Tip: There is a modernized version called [Tuner X](#) that is available for Windows and Android devices (works with Phoenix 5 and [Phoenix Pro](#)).

2.13.1 Getting sensor data

Sensor data can also be retrieved using the base FRC API available in LabVIEW/C++/Java. See WPI/NI/FRC documentation for how.

2.13.2 DriverStation Logs

Driver Station logs are automatically generated during normal FRC use. This includes current logging on all PDP Wago channels. Review WPI/NI/FRC documentation for how leverage this.

2.13.3 2015 Kick off Kit PDPs

There is a known issue with 2015 Kickoff-Kit PDPs where the PDP will not appear on CAN bus and/or LEDs will be red, despite all other devices on the CAN bus functioning properly. This is due to an ESD vulnerability that only exists in the initial manufacture run in 2014. Every season PDP afterwards does not have this issue.

Manufacture date of the PDP can be checked in Tuner. Any PDP with a manufacture date of August 14, 2014 may have this issue. No other PDPs (even those with other 2014 manufacture dates) are known to be affected.

Robot Controller Install		CAN Devices	Control	Config	Self-Test	Plot
Devices (Count:5)	Software Status	Hardware	ID	Firmware Version	Manufacturer Date	Bootlo
 CANifier (Device ID 0)	Running Application.	CANifier	00	0.40		1.0
 PDP (Device ID 0)	Running Application.	PDP	00	1.40	Aug 14, 2014	1.0
 PDP (Device ID 13)	Running Application.	PDP	13	1.30	Nov 3, 2014	3.1
 Talon SRX (Device ID 1)	Running Application.	Talon SRX	01	4.11	Nov 3, 2014	2.6
 Talon SDX (Device ID 2)	Running Application.	Talon SDX	02	4.11	Aug 14, 2015	3.2

These PDPs do correctly provide power and terminate the CAN bus with no compromises. However, the current measurement features may not be correct or available on this version of PDP. If such a PDP is re-used or re-purposed, we recommend using it on your practice robot or for bench setups, and not for competition.

2.14 Bring Up: Pigeon IMU

2.14.1 Power Boot

Power boot the robot and wait for Pigeon IMU LED pattern indicating device has settled. This will appear as a symmetric blink pattern (equal time on each side's LED). If the LED strobe is weighted to one side (more time on one side than the other) then IMU is still settling. Typical settle time is four seconds.

Warning: Ribbon cabled Pigeon may not appear in CAN devices if Talon SRX firmware is too old.

Warning: Ribbon cabled Pigeon may not work as a remote sensor unless [Pigeon Firmware](#) is at least 4.13.

2.14.2 Phoenix Tuner

Open Phoenix tuner and use the Self-test Snapshot feature to confirm values. Rotate IMU and confirm Yaw moves as expected.

Tip: There is a modernized version called [Tuner X](#) that is available for Windows and Android

devices (works with Phoenix 5 and [Phoenix Pro](#)).

Note: Moving counter-clockwise is interpreted as a positive change.

2.14.3 Pigeon API

Create a Pigeon IMU object in your robot application and poll the Yaw value.

Warning: In a competition robot application it is **strongly recommended** to first **confirm that `getState()` yields a Ready State**. Otherwise the IMU values will not be useful.

```
import com.ctre.phoenix.sensors.PigeonIMU;
public class Robot extends TimedRobot {
    PigeonIMU _pigeon = new PigeonIMU(0);
    int _loopCount = 0;

    public void teleopPeriodic() {
        if(_loopCount++ > 10)
        {
            _loopCount = 0;
            double[] ypr = new double[3];
            _pigeon.getYawPitchRoll(ypr);
            System.out.println("Pigeon Yaw is: " + ypr[0]);
        }
    }
}
```

Tip: Image below can be dragged/dropped into LabVIEW editor.

Confirm that the output matches the Self-test Snapshot results.

If using LabVIEW plotter or SmartDash plotting, send the Yaw value into the plotted channel. Then confirm Yaw value provides a smooth curve while robot is rotated by hand.

2.14.4 Temperature Calibration

The greatest source of yaw drift in the FRC use case is drift due to changes in temperature. This can be compensated by running the temperature self-calibration once.

In previous seasons this can be invoked via Phoenix API.

However, starting in 2019, you can manually enter temperature compensation mode by opening the Pigeon IMU Cal tab (go to Windows in the top menu bar).

Select the specific Pigeon in the top drop down, and press the Enter Temperature Calibration button. Self-test Snapshot can be used to monitor the progress.

Note: There is no harm in starting a temp calibration, and aborting by power cycling. Previ-

ous temp calibration (if present) is overridden at the very end of the procedure. See Self-test Snapshot for current state of Temperature Calibration and Compensation.

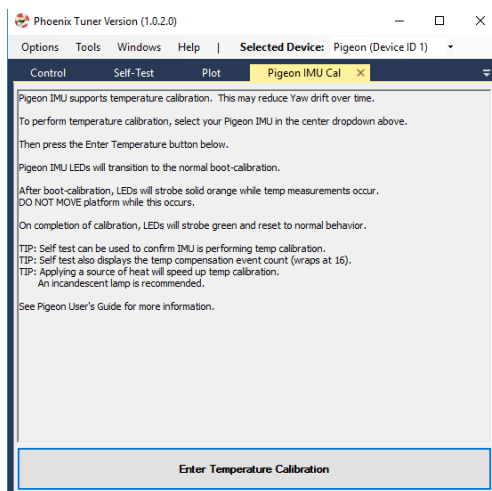

Temperature Calibration procedure

When temperature-calibrating the Pigeon, the user should first observe the impact of temperature by cleanly booting the system and observing the critical values (such as yaw) while heating the Pigeon. This can be done by self-testing the Pigeon in Phoenix Tuner or printing the critical values in a robot application.

1. Place the Pigeon on a reasonably level surface such that it stays still.
2. After it boot calibrates, heat the Pigeon. A simple off the shelf halogen desk lamp is sufficient to heat.
3. Observe the critical values as the temperature increases. Some IMU chips are very temperature sensitive and will experience a drift in yaw by over 40 degrees, while others may not drift at all.

After having observed the impact of temperature on the critical values, you can go about calibrating it from that drift.

1. Ensure Pigeon is cool before beginning temperature calibration. This can be confirmed with a Self-test Snapshot or by printing the temperature in a robot application.
2. Enter temperature calibration mode. This is done either using the API or using Phoenix Tuner

3. Heat the Pigeon.
4. Once the Pigeon has seen a sufficient range of temperatures, it will momentarily blink green, then cleanly boot-calibrate.
5. Perform a Self-test Snapshot on the Pigeon. It should read "Temperature calibration exists" along with a description of whether it will use it or not and for what reason if not.

Build:Jan 1 2019 21:19:47

Press "Refresh" to close.

6. After the Pigeon has boot-calibrated, re-observe the effect of temperature on the critical values' drift using the above procedure.
7. While re-observing, notice the tempCompensationCount tracker tick up as the Pigeon compensates for temperature.

2.15 Bring Up: Pigeon 2.0

2.15.1 Power Boot

Pigeon 2.0 measurements can be obtained immediately after boot.

2.15.2 Phoenix Tuner

Open Phoenix tuner and use the Self-test Snapshot feature to confirm values. Rotate IMU and confirm Yaw moves as expected.

Self-Test Snapshot Copy To Clipboard Blink / Clear Faults

Updating [http://127.0.0.1:1250] CTRE Devices... Ok Server Version: 1.9.1 (Feb 3 2022,23:24:09)

Tip: There is a modernized version called [Tuner X](#) that is available for Windows and Android devices (works with Phoenix 5 and [Phoenix Pro](#)).

Note: Moving counter-clockwise is interpreted as a positive change.

2.15.3 Pigeon API

Create a Pigeon 2 object in your robot application and poll the Yaw value.

Note: Pigeon 2.0 uses a different class than Pigeon 1. It is named Pigeon2 instead of PigeonIMU.

```
import com.ctre.phoenix.sensors.Pigeon2;
public class Robot extends TimedRobot {
    Pigeon2 _pigeon = new Pigeon2(0, "rio");
    int _loopCount = 0;

    public void teleopPeriodic() {
        if(_loopCount++ > 10)
        {
            _loopCount = 0;
            double yaw = _pigeon.getYaw();
            System.out.println("Pigeon Yaw is: " + yaw);
        }
    }
}
```

Confirm that the output matches the Self-test Snapshot results.

If using LabVIEW plotter or SmartDash plotting, send the Yaw value into the plotted channel. Then confirm Yaw value provides a smooth curve while robot is rotated by hand.

2.16 Bring Up: CANifier

2.16.1 Phoenix Tuner

Using Self-test Snapshot, confirm all sensor inputs required by the robot application.

If using Limit switches, assert each switch one at time. Self-test Snapshot after each transition to confirm wiring.

If using Quadrature or Pulse width sensor, rotate sensor while performing Self-test Snapshot to confirm sensor values.

Tip: There is a modernized version called [Tuner X](#) that is available for Windows and Android devices (works with Phoenix 5 and [Phoenix Pro](#)).

2.16.2 LED Strip Control

See [CANifier user's guide](#) for wiring and controlling LED Strip.

2.16.3 CANifier API

Create a CANifier object in your robot application and poll whatever sensor you have connected to it or the bus voltage

```
import com.ctre.phoenix.CANifier;
public class Robot extends TimedRobot {
    CANifier _canifier = new CANifier(0);
    int _loopCount = 0;

    public void teleopPeriodic() {
        if(_loopCount++ > 10)
        {
            _loopCount = 0;
            System.out.println("Bus voltage is: " + _canifier.getBusVoltage());
        }
    }
}
```

Confirm output matches Self-test Snapshot results.

2.17 Bring Up: CANCoder

Note: As of late August 2022, there are multiple hardware versions of CANCoder available. This is due to the ongoing worldwide chip shortage causing CTR electronics to replace the original processor with a substitute. This new version of CANCoder requires a different firmware, but is otherwise functionally identical to the original. For details on how to determine what hardware version a CANCoder is, look at the [CANCoder Versions](#) section.

2.17.1 Magnet Placement

Using the CANCoder User's Guide, verify that magnet placement is correct for the CANCoder.

2.17.2 Phoenix Tuner

Open Phoenix tuner and use the Self-test Snapshot feature to confirm values. By default, the position value is in units of degrees.

Tip: There is a modernized version called [Tuner X](#) that is available for Windows and Android devices (works with Phoenix 5 and [Phoenix Pro](#)).

2.17.3 Choose Sensor Direction

Choose which direction of the sensor is positive using the “Sensor Direction” config setting.

By default, positive direction is counter-clockwise rotation of the magnet when looking at the magnet side of the CANCoder.

Use the self-test snapshot to confirm the sensor value changes as expected for the chosen direction.

2.17.4 Choose Sensor Boot-Initialization Strategy

Select whether the CANCoder position should initialize to 0 or initialize to the absolute position measurement.

Robot Controller Install	CAN Devices	Control	Config ×								
▼ Advanced Sensor and Meas <table> <tr> <td>Velocity Period</td> <td>100</td> </tr> <tr> <td>Velocity Window</td> <td>64</td> </tr> </table>				Velocity Period	100	Velocity Window	64

Sensor Initialization Strategy	BootToZero										
▼ Unit Coefficient And String <table> <tr> <td>Sensor Coefficient</td> <td>0.087890625</td> </tr> <tr> <td>Sensor Time Base</td> <td>PerSecond</td> </tr> <tr> <td>Unit String</td> <td>deg</td> </tr> </table>				Sensor Coefficient	0.087890625	Sensor Time Base	PerSecond	Unit String	deg		
Sensor Coefficient	0.087890625										
Sensor Time Base	PerSecond										
Unit String	deg										

2.17.5 Choose Absolute Sensor Range

Select whether the absolute position value should range from 0 degrees to 360 degrees or -180 to +180.

Robot Controller Install	CAN Devices	Control	Config ×								
▼ Advanced Sensor and Meas <table> <tr> <td>Velocity Period</td> <td>100</td> </tr> <tr> <td>Velocity Window</td> <td>64</td> </tr> </table>				Velocity Period	100	Velocity Window	64				
Velocity Period	100										
Velocity Window	64										
▼ Custom Params <table> <tr> <td>Custom Param 0</td> <td>0</td> </tr> <tr> <td>Custom Param 1</td> <td>0</td> </tr> </table>				Custom Param 0	0	Custom Param 1	0				
Custom Param 0	0										
Custom Param 1	0										
▼ Internal Sensor <table> <tr> <td>Absolute Sensor Range</td> <td>Range_0_to_360</td> </tr> <tr> <td>Magnet Offset (deg)</td> <td>0</td> </tr> <tr> <td>Sensor Direction</td> <td>False</td> </tr> <tr> <td>Sensor Initialization Strategy</td> <td>BootToZero</td> </tr> </table>				Absolute Sensor Range	Range_0_to_360	Magnet Offset (deg)	0	Sensor Direction	False	Sensor Initialization Strategy	BootToZero
Absolute Sensor Range	Range_0_to_360										
Magnet Offset (deg)	0										
Sensor Direction	False										
Sensor Initialization Strategy	BootToZero										
▼ Unit Coefficient And String <table> <tr> <td>Sensor Coefficient</td> <td>0.087890625</td> </tr> <tr> <td>Sensor Time Base</td> <td>PerSecond</td> </tr> <tr> <td>Unit String</td> <td>deg</td> </tr> </table>				Sensor Coefficient	0.087890625	Sensor Time Base	PerSecond	Unit String	deg		
Sensor Coefficient	0.087890625										
Sensor Time Base	PerSecond										
Unit String	deg										

2.17.6 Choose Absolute Sensor Offset

Choose an offset for the 0 point of the absolute measurement.

By default, this 0 point is when the magnet's north aligns with the LED on the CANCoder.

Note: For mechanisms with a fixed range of motion, the offset should be set so that the discontinuity of the absolute measurement (ie, the rollover from 360 -> 0 or 180 -> -180) does not occur in the mechanism's range of motion.

2.17.7 CANCoder API

Create a CANCoder object in your robot project and poll the position value.

```
import com.ctre.phoenix.sensors.CANCoder;
public class Robot extends TimedRobot {

    CANCoder _coder = new CANCoder(1);
    int _loopCount = 0;

    public void teleopPeriodic() {
        if(_loopCount++ > 10)
        {
            _loopCount = 0;
            int degrees = _coder.getPosition();
            System.out.println("CANCoder position is: " + degrees);
        }
    }
}
```

Confirm that the output matches the self-test snapshot results.

2.17.8 CANCoder Versions

CANCoder has two hardware versions, the original “CANCoder” and the newer “CANCoder vers. H” or “CANCoder vH” for short. Each hardware version has a unique crf that’s associated with it, which means it is not possible to flash “CANCoder” firmware onto a “CANCoder vH” or vice versa.

Identification

Connect Tuner to the robot in order to identify what hardware version a CANCoder is, as the version is displayed in the Hardware column. In addition, the Manufacture Date, Bootloader Revision, and Hardware Version columns will all be different between original CANCoders and CANCoder vH’s. Below is a screenshot of two CANCoders, one original CANCoder and another CANCoder vH, to better illustrate this.

Firmware Upgrade

Firmware upgrading the CANCoder vH is performed the same way as the original CANCoder. Select the CRF and update the device.

Note: CANCoder vH’s have a different firmware CRF than original CANCoders. Make sure the filename is correct.

If the wrong CRF is selected (such as an original CANCoder crf for a CANCoder vH), Tuner will fail with CTRE_DI_InvalidCrfWrongProduct in the bottom right of the screen, and the text box will report “Selected CRF is for the wrong product”. A screenshot of this state is below.

2.18 Bring Up: CANDle

For wiring see the CANDle Hardware User Manual on the product page:

<https://store.ctr-electronics.com/candle/>

By default CANDle is configured to use GRB addressable LED strips. Use Phoenix Tuner to change the LED Strip Type config to match the physical LED strip being used.

Note: CANDle's latest features require using [this development build of Phoenix](#) (via the [online install](#) method) along with [latest CANDle firmware \(21.1.1.0\)](#).

The development release is a small feature-improvement release based on the latest public full release - while it hasn't gone through the entire rigorous test process for a full release the specific changes are minor and well-tested so it's safe to use on your robot.

The dev release enables use of the multi-animation CANDle features without waiting for the next full release.

2.18.1 CANDle API

CANDle's API calls can be found here: [C++](#) | [Java](#)

2.18.2 Examples

There is a basic example for using CAndle here: [C++](#) | [Java](#)

An advanced example using multiple animations can be found here: [Java](#)

2.19 Bring Up: Talon FX/SRX and Victor SPX

At this point all Talon and Victors should appear in Tuner with up to date firmware. The next goal is to drive the motor controller manually. This is done to confirm/test:

- Motor and motor wiring
- Transmission/Linkage
- Mechanism design
- Motor Controller drive (both directions)
- Motor Controller sensor during motion

Note: Talon FX/SRX and Victor SPX can be used with PWM or CAN bus. This document covers the CAN bus use-case.

Before we enable the motor controller, first check or reset the configs in the next section.

2.19.1 Factory Default Motor Controller

Open the config view to see all persistent settings in the motor controller. This can be done in the config tab (Windows => Config).

Select the Victor or Talon in the center-top dropdown. This will reveal all persistent config settings.

Press Factory Default to default the motor controller settings so that it has predictable behavior.

Tip: There is a modernized version called [Tuner X](#) that is available for Windows and Android devices (works with Phoenix 5 and [Phoenix Pro](#)).

Tip: Right-click anywhere in the property inspector and select Collapse-all to collapse each config group.

Tip: Other configs can be set in this view for testing purposes. For example, you may want to restrict the maximum output for testing via the Peak output settings under “Motor Output”.

Tip: When a setting is modified, it is set to bold to indicate that it is pending. The bold state will clear after you Save.

Tip: If changing a config live in the robot controller, use the Refresh/Revert button to confirm setting in Tuner.

Note: CTRE devices can be factory defaulted via the API, and through the B/C mechanical button.

Note: Neutral Mode will not change during factory default as it is stored separately from the other persistent configs.

2.19.2 Configuration

Configurable settings are persistent settings that can be modified via the Phoenix API (from robot code) or via Tuner (Config tab). They can also be factory defaulted using either method.

Configs are modified via the config* routines and LabVIEW Vis. There are two general methods for robust operation of a robot. Additionally you can modify the configs via Tuner.

Method 1 - Use the configAll API

Starting with 2019, there is a single routine/VI for setting all of the configs in a motor controller. This ensures that your application does not need to be aware of every single config in order to reliably configure a fresh or unknown motor controller.

This is the recommend API for new robot projects.

Tip: Config structure/object defaults all values to their factory defaults. This means generally you only need to change the settings you care about.

Tip: When using C++/Java, leverage the IntelliSense (Auto-complete) features of the IDE to quickly discover the config settings you need.

Method 2 - Factory Default and config* routines

Phoenix provides individual config* routines for each config setting. Although this is adequate when the number of configs was small, this can be difficult to manage due to the many features/configs in the CTRE motor controllers.

If using individual config routines, we recommend first calling the configFactoryDefault routine/VI to ensure motor controller is restored to a known state, thus allowing you to only config the settings that you intend to change.

This is recommend for legacy applications to avoid porting effort.

Method 3 - Use Tuner

Tuner can be used to get/set/export/import the configs.

However, it is **highly recommended to ultimately set them via the software API**. This way, in the event a device is replaced, you can rely on your software to properly configure the new device, without having to remember to use Tuner to apply the correct values.

A general recommendation is to:

- Configure all devices during robot-bootup using the API,
- Use Tuner to dial values quickly during testing/calibration.
- Export the settings so they are not lost.
- Update your software config values so that Tuner is no longer necessary.

Control Signals

The majority of the behavior in the Talon/Victor is controlled via configs, however there is a small number of control signals that are controlled via the API.

This list includes:

- Current Limit **Enable** (though the thresholds are configs)
- Voltage Compensation **Enable** (though the nominal voltage is a config)
- Control Mode and Target/Output demand (percent, position, velocity, etc.)
- Invert direction and sensor phase
- Closed-loop slot selection [0,3] for primary and aux PID loops.
- Neutral mode override (convenient to temporarily override configs)
- Limit switch override (convenient to temporarily override configs)
- Soft Limit override (convenient to temporarily override configs)
- Status Frame Periods

These control signals do not require periodic calls to ensure they “stick”. All of the above signals are automatically restored even after motor controller is power cycled during use except for Status Frame Periods, which can be manually restored by polling for device resets via `hasResetOccurred()`.

Note: WPI motor safety features may require periodic calls to `Set()` if team software has chosen to enable it.

Note: The override control signals are useful for applications that require temporarily disabling or changing behavior. For example, overriding-disable the soft limits while performing a self-calibration routine to tare sensors, then restoring soft limits for robot operation.

Note: The routines to manipulate control signals are not prefixed with `config*` to highlight that they are not configs

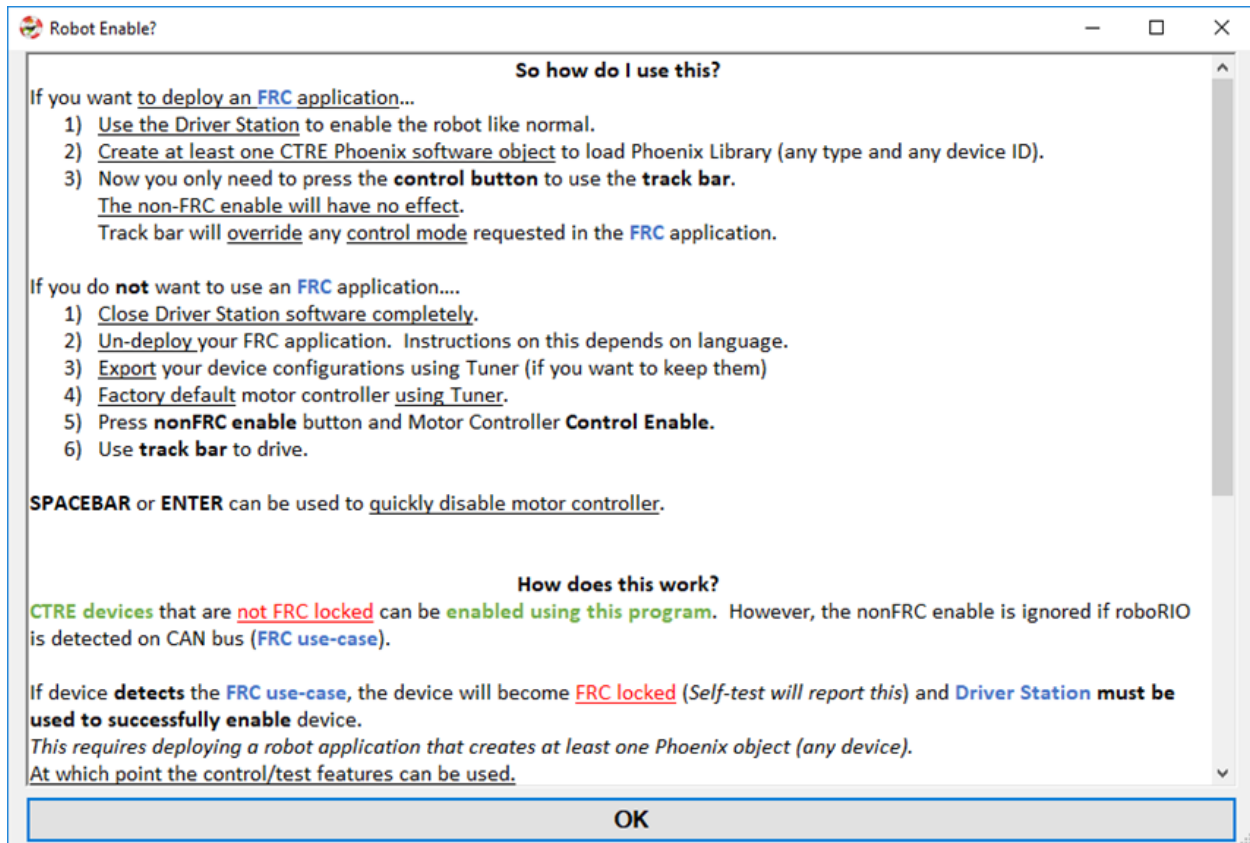

2.19.3 Test Drive with Tuner

Navigate to the control tab to view the control interface. Notice there are two enable/disable buttons. One is for non-FRC style robot-enable (alternative to the Driver Station enable), and one is for Motor Controller Control-Enable.

Press on the question mark next to the robot disabled/enabled button.

This will reveal the full explanation of how to safely enable your motor controller. Follow the appropriate instructions depending on if you want to use Driver Station for your robot-enable.

Setting up non-FRC Control

In order to enable without the Driver Station you must use a non-roboRIO platform and disconnect the roboRIO from the CAN bus.

With an FRC roboRIO, you must *always* use the Driver Station to enable.

Confirm FRC Unlock

Self-test Snapshot Motor Controller to confirm device FRCLocked = 0.

If device is FRC Locked (=1), use factory default in the config tab to clear the state. Note that if an FRC roboRIO is on the CAN bus, the motor controller will immediately FRC Lock again.

Note: Use the config export tool if you need to keep your config settings.

Control tab

Press both Robot Enabled and Control Enabled. At this point you can use the track bar to drive the Victor/Talon.

Note: If you do connect with a roboRIO, the Talon/Victor will FRC Lock again. At which point you must use the driver station to enable, and you no longer need to use the non-FRC Robot enable in Tuner.

Note: Spacebar or enter can be used to clear the control tab and neutral the selected motor

Phoenix

controller.

Plot tab

Now open the Plot window. Drive the motor controller while observing the plot. Confirm the blue motor output curve matches LED behavior and trackbar. Confirm motor movement follows expectations.

Note: Press the Plot enable button to effectively pause the plot for review

Note: Use the Zoom buttons to select whether the mouse adjust the Y or X axis.

Note: If using a Victor SPX, current-draw will always read zero (SPX does not have current-measurement features).

Tip: Plot can be used anytime, regardless of what is commanding the motor controller (FRC or non-FRC).

2.19.4 Test Drive with Robot Controller

Next we will create control software in the roboRIO. Currently this is necessary for more advanced control. This is also required for controlling your robot during competition.

Tip: The latest version of Tuner allows for testing most closed-loop control modes without writing software.

Java: Sample driving code

Below is a simple example that reads the Joystick and drives the Talon

```
package frc.robot;

import com.ctre.phoenix.motorcontrol.ControlMode;
import com.ctre.phoenix.motorcontrol.can.TalonSRX;

import edu.wpi.first.wpilibj.Joystick;
import edu.wpi.first.wpilibj.TimedRobot;

public class Robot extends TimedRobot {
    TalonSRX _talon0 = new TalonSRX(0); // Change '0' to match device ID in Tuner. Use
    ↪ VictorSPX for Victor SPXs
    Joystick _joystick = new Joystick(0);

    @Override
    public void teleopPeriodic() {
```

(continues on next page)

(continued from previous page)

```
double stick = _joystick.getRawAxis(1);  
_talon0.set(ControlMode.PercentOutput, stick);  
}  
}
```

Tip: Image below can be dragged/dropped into LabVIEW editor.

Deploy the project, and confirm success.

Note: WPI's terminal output may read "Build" successful despite the project was deployed.

```

8  package frc.robot;
9
10 import com.ctre.phoenix.motorcontrol.ControlMode;
11 import com.ctre.phoenix.motorcontrol.can.TalonSRX;
12
13 import edu.wpi.first.wpilibj.Joystick;
14 import edu.wpi.first.wpilibj.TimedRobot;
15
16 public class Robot extends TimedRobot {
17     TalonSRX _talon0 = new TalonSRX(0);
18     Joystick _joystick = new Joystick(0);
19
20     @Override
21     public void teleopPeriodic() {
22         double stick = _joystick.getRawAxis(0);
23         _talon0.set(ControlMode.PercentOutput, stick);
24     }
25 }
26

```

```

Deprecated Gradle features were used in this build, making it incompatible with Gradle 6.0.

Use '--warning-mode all' to show the individual deprecation warnings.

See https://docs.gradle.org/5.0/userguide/command_line_interface.html#sec:command_line_warnings

BUILD SUCCESSFUL in 5s

10 actionable tasks: 8 executed, 2 up-to-date

Note: Before you enable the DS, spin the Joystick axis so it reaches the X and Y extremities are reached. USB Gamepads calibrate on-the-fly so if the Gamepad was just inserted into the DS, it likely has not auto detected the max mechanical range of the sticks.

Note: Make sure joystick is detected by the DS before enabling.

Note: getRawAxis may not return a positive value on forward-stick. Confirm this by watching Talon/Victor LED. Green suggests a positive output.

Enable the Driver Station and confirm:

- motor drive in both directions using gamepad stick.

- motor controller LEDs show green for forward and red for reverse

Disable Driver Station after finished testing.

Note: If the LED is solid orange than use Tuner to determine the cause. Self-test Snapshot will report the current state of the motor controller (do this while troubleshooting). Confirm firmware is up to date.

2.19.5 Open-Loop Features

After some rudimentary testing, you will likely need to configure several open-loop features of the Talon SRX and Victor SPX.

Note: We recommend configuring Inverts and Followers first.

Inverts

To determine the desired invert of our motor controller, we will add two more lines of call. SetInverted is added to decide if motor should spin clockwise or counter clockwise when told to move positive/forward (green LEDs).

Note: The selected sensor's values are also inverted accordingly so **the sensor phase does not need to be adjusted** based on motor inversion.

We also multiply the joystick so that forward is positive (intuitive). This can be verified by watching the console print in the Driver Station.

```
package frc.robot;
import com.ctre.phoenix.motorcontrol.*;
import com.ctre.phoenix.motorcontrol.can.*;

import edu.wpi.first.wpilibj.Joystick;
import edu.wpi.first.wpilibj.TimedRobot;

public class Robot extends TimedRobot {
    TalonSRX _talon0 = new TalonSRX(0);
    Joystick _joystick = new Joystick(0);

    @Override
    public void teleopInit() {
        _talon0.setInverted(false); // pick CW versus CCW when motor controller is
        ↪ positive/green
    }

    @Override
    public void teleopPeriodic() {
        double stick = _joystick.getRawAxis(1) * -1; // make forward stick positive
        System.out.println("stick:" + stick);
    }
}
```

(continues on next page)

(continued from previous page)

```
    _talon0.set(ControlMode.PercentOutput, stick);  
  }  
}
```

Tip: Image below can be dragged/dropped into LabVIEW editor.

Talon FX Specific Inverts

Talon FX has a new set of inverts that are specific to it, *TalonFXInvertType.Clockwise* and *TalonFXInvertType.CounterClockwise*. These new inverts allow the user to know exactly what direction the Falcon 500 will spin. These inverts are from the perspective of looking at the face of the motor.

Below is an image demonstrating the Falcon's **Clockwise** rotation:

And below is the Falcon's **CounterClockwise** rotation:

Follower

If a mechanism requires multiple motors, then there are likely multiple motor controllers. The Follower feature of the Talon FX/SRX and Victor SPX is a convenient method to keep two or more motor controller outputs consistent. If you have an external sensor for closed-looping, connect that to the “master” Talon SRX (unless it is a remote sensor such as CAN-coder/CANifier/Pigeon).

Below we’ve added a new Victor to follow Talon 0.

Generally, a follower is intended to match the direction of the master, or drive in the opposite direction depending on mechanical orientation. In previous seasons teams would have to update the bool true/false of the follower to match or oppose the master manually.

Starting in 2019, C++/Java users can set the `setInverted(InvertType)` to instruct the motor controller to either match or oppose the direction of the master instead.

```
package frc.robot;

import com.ctre.phoenix.motorcontrol.*;
import com.ctre.phoenix.motorcontrol.can.*;

import edu.wpi.first.wpilibj.Joystick;
import edu.wpi.first.wpilibj.TimedRobot;

public class Robot extends TimedRobot {
    TalonSRX _talon0 = new TalonSRX(0);
    VictorSPX _victor0 = new VictorSPX(0);
    Joystick _joystick = new Joystick(0);

    @Override
    public void teleopInit() {
        _victor0.follow(_talon0);
    }
}
```

(continues on next page)

(continued from previous page)

```

_talon0.setInverted(false); // pick CW versus CCW when motor controller is
↳ positive/green
_victor0.setInverted(InvertType.FollowMaster); // match whatever talon0 is
//_victor0.setInverted(InvertType.OpposeMaster); // opposite whatever talon0 is
}

@Override
public void teleopPeriodic() {
    double stick = _joystick.getRawAxis(1) * -1; // make forward stick positive
    System.out.println("stick:" + stick);

    _talon0.set(ControlMode.PercentOutput, stick);
}
}

```

Tip: Image below can be dragged/dropped into LabVIEW editor.

Note: LabVIEW does not support using InvertType to follow master or oppose master

Enable the Driver Station and slowly drive both MCs from neutral. Confirm both LEDs are blinking the same color.

Disable Driver Station when complete.

To confirm motor controllers are truly driving in the same direction, disconnect the master motor controller from its motor.

Enable the Driver Station and confirm follower motor direction matches previously measured master motor direction.

Disable Driver Station when complete.

Open Tuner and select the master motor controller.

Open plot tab and enable plotter while driving motor controller

Confirm current plot is appropriate. If motors are free-spinning, then current should be near 0 if motor output is constant. When testing drive train, the robot should be rested on a crate/tote to ensure all wheels spin freely.

Select follower motor in Tuner, and confirm current via plot.

Note: Follower mode can be canceled by calling set() with any other control mode, or calling

neutralOutput().

Note: Calling follow() in the periodic loop is not required, but also does not affect anything in a negative way.

Controlling Followers with Phoenix Tuner

Oftentimes you want to test/tune a mechanism with a master motor controller and one or more followers. This can be accomplished with Phoenix Tuner in the same manner as if there was only one controller, **as long as the followers are configured to follow the master**. This means you **cannot** run a temporary diagnostic server to control multiple motor controllers at the same time.

It is imperative to make sure the followers are configured correctly by **following the steps above**. The followers will use their settings from the user application, even when following a master controlled by Tuner.

Tip: This is the recommended way to tune two or more mechanically linked motors. By having one motor controller as a master, it will handle the PID closed looping while all followers match the applied output of the master.

Neutral Mode

You may note that when the motor output transitions to neutral, the motors free spin (coast) in the last direction they were driven. If the Talon/Victor is set to “coast” neutral mode, then this is expected. The neutral mode can also be set to “brake” to electrically common the motor leads during neutral, causing a deceleration that combats the spinning motor motion.

Tip: You can use Talon FX’s ConfigStatorCurrentLimit method to dial in how strong the brake is.

Note: SetNeutralMode() can be used change the neutral mode on the fly.

```
TalonSRX talon = new TalonSRX(0);  
talon.setNeutralMode(NeutralMode.Brake);
```

Tip: Image below can be dragged/dropped into LabVIEW editor.

Follower motor controllers have separate neutral modes than their masters, so you must choose both. Additionally, you may want to mix your neutral modes to achieve a partial electric brake when using multiple motors.

Neutral Deadband

A device's neutral deadband is the region where the controller demotes its output to neutral. This can be configured in your robot code, with a default value of 0.04 or 4%, and a range of [0.001, 0.25] or [0.1%, 25%].

```
_talon.configNeutralDeadband(0.001); /* Configures _talon to use a neutral deadband of 0.1% */
```

Talon FX has 3 different deadband strategies based on its state. They are *Simple*, *Continuous*, and *None*.

A *Simple* deadband will demote any requested output within the region to neutral, and otherwise uphold the requested demand. An example of this is with a configured deadband of 4% and a requested output of 4% will be 0%, 5% output will be 5%, and 100% will be 100%. This is used in the majority of circumstances so it's obvious that the requested output is the applied output outside the neutral deadband.

A *Continuous* deadband is similar to a simple deadband in that it demotes any requested output within the region to neutral, but outside the region it will scale the applied output so it's continuous out of the deadband thresholds. This allows for a smooth transition out of neutral. With a 4% deadband, a requested output of 4% will result in an applied output of 0%, requesting 5% will bring it to 1%, and 100% will be 100%.

A *None* deadband will not uphold the deadband whatsoever. A deadband of 4% with 4% requested output will apply 4%, 5% is 5%, and 100% is 100%. This is used only in follower mode so you don't have to configure the deadband of your followers, only of the master.

The below graph highlights this, exaggerating the effect to make it obvious.

The below table details what neutral deadband strategy the Talon FX uses under the various states.

Table 4: Talon FX Neutral Deadband Strategies

Mode	Condition	Deadband Type
PWM Control	X	Continuous
Percent Output	Voltage Compensation Disabled	Continuous
Percent Output	Voltage Compensation Enabled	Simple
Closed Loop	X	Simple
Auxiliary Follower	X	Simple
Follower	X	None

Ramping

The motor controller can be set to honor a ramp rate to prevent instantaneous changes in throttle. This ramp rate is in effect regardless of which mode is selected (throttle, follower, or closed-loop).

Ramp can be set in time from neutral to full using `configOpenLoopRampRate()`.

Note: `configClosedLoopRampRate()` can be used to select the ramp during closed-loop (sensor) operations.

Note: The slowest ramp possible is ten seconds (from neutral to full), though this is quite excessive.

```
TalonSRX talon = new TalonSRX(0);
talon.configOpenloopRamp(0.5); // 0.5 seconds from neutral to full output (during
↪ open-loop control)
talon.configClosedloopRamp(0); // 0 disables ramping (during closed-loop control)
```

Tip: Images below can be dragged/dropped into LabVIEW editor.

Peak/Nominal Outputs

Often a mechanism may not require full motor output. The application can cap the output via the peak forward and reverse config setting (through Tuner or API).

Additionally, the nominal outputs can be selected to ensure that any non-zero requested motor output gets promoted to a minimum output. For example, if the nominal forward is set to +0.10 (+10%), then any motor request within (0%, +10%) will be promoted to +10% assuming request is beyond the neutral dead band. This is useful for mechanisms that require a minimum output for movement, and can be used as a simpler alternative to the KI (integral) component of closed-looping in some circumstances.

Voltage Compensation

Talon FX/SRX and Victor SPX can be configured to adjust their outputs in response to the battery voltage measurement (in all control modes). Use the voltage compensation saturation config to determine what voltage represents 100% output.

Then enable the voltage compensation using `enableVoltageCompensation()`.

Advanced users can adjust the Voltage Measurement Filter to make the compensation more or less responsive by increasing or decreasing the filter. This is available via API and via Tuner

```
TalonSRX talon = new TalonSRX(0);
talon.configVoltageCompSaturation(11); // "full output" will now scale to 11 Volts
↳ for all control modes when enabled.
talon.enableVoltageCompensation(true); // turn on/off feature
```

Tip: Image below can be dragged/dropped into LabVIEW editor.

Current Limit

Legacy API

Talon FX/SRX supports current limiting in all control modes.

The limiting is characterized by three configs:

- Peak Current (Amperes), threshold that must be exceeded before limiting occurs.
- Peak Time (milliseconds), thresholds that must be exceed before limiting occurs
- Continuous Current (Amperes), maximum allowable current after limiting occurs.

```
TalonSRX talon = new TalonSRX(0);  
talon.configPeakCurrentLimit(30); // don't activate current limit until current  
↳ exceeds 30 A ...  
talon.configPeakCurrentDuration(100); // ... for at least 100 ms  
talon.configContinuousCurrentLimit(20); // once current-limiting is activated, hold  
↳ at 20A  
talon.enableCurrentLimit(true);
```

Tip: Image below can be dragged/dropped into LabVIEW editor.

If enabled, Talon SRX will monitor the supply-current looking for a conditions where current has exceeded the Peak Current for at least Peak Time. If detected, output is reduced until current measurement is at or under Continuous Current.

Note: If Peak current limit is set less than continuous limit, peak current limit will be set equal to continuous current limit.

Once limiting is active, current limiting will deactivate if motor controller can apply the requested motor output and still measure current-draw under the Continuous Current Limit.

After setting the three configurations, current limiting must be enabled via `enableCurrentLimit()` or LabVIEW VI.

Note: Use Self-test Snapshot to confirm if Current Limiting is occurring

Note: If peak limit is less than continuous limit, peak is set equal to continuous

Note: If you only want continuous limiting, you should set peak limit to 0

New API in 2020

Talon FX supports both stator(output) current limiting and supply(input) current limiting.

Supply current is current that's being drawn at the input bus voltage. Stator current is current that's being drawn by the motor.

Supply limiting (supported by Talon SRX and FX) is useful for preventing breakers from tripping in the PDP.

Stator limiting (supported by Talon FX) is useful for limiting acceleration/heat.

The new API leverages the `configSupplyCurrentLimit` and `configStatorCurrentLimit` routines. The configs are similar to the existing legacy API, but the configs have been renamed to better

communicate the design intent. For example, instead of `configPeakCurrentLimit`, the setting is referred to as `triggerThresholdCurrent`.

```
/**
 * Configure the current limits that will be used
 * Stator Current is the current that passes through the motor stators.
 * Use stator current limits to limit rotor acceleration/heat production
 * Supply Current is the current that passes into the controller from the supply
 * Use supply current limits to prevent breakers from tripping
 *
 *
 *                                     enabled |
↪ Limit(amp) | Trigger Threshold(amp) | Trigger Threshold Time(s) */
_tal.configStatorCurrentLimit(new StatorCurrentLimitConfiguration(true,    20,
↪      25,                    1.0));
_tal.configSupplyCurrentLimit(new SupplyCurrentLimitConfiguration(true,   10,
↪      15,                    0.5));
```

An example of this is available on our [Github Examples](#) repository

2.19.6 Reading status signals

The Talon FX/SRX and Victor SPX transmit most of their status signals periodically, i.e. in an unsolicited fashion. This improves bus efficiency by removing the need for “request” frames, and guarantees that the signals necessary for the wide range of use cases they support are available.

These signals are available in API regardless of what control mode the Talon SRX is in. Additionally the signals can be polled using Phoenix Tuner using the Self-test Snapshot button.

Included in the list of signals are:

- Quadrature Encoder Position, Velocity, Index Rise Count, Pin States (A, B, Index)
- Analog-In Position, Analog-In Velocity, 10bit ADC Value,
- Battery Voltage, Current, Temperature
- Fault states, sticky fault states,
- Limit switch pin states
- Applied Throttle (duty cycle) regardless of control mode.
- Applied Control mode: Voltage % (duty-cycle), Position/Velocity closed-loop, or follower.
- Brake State (coast vs brake)
- Closed-Loop Error, the difference between closed-loop set point and actual position/velocity.
- Sensor Position and Velocity, the signed output of the selected Feedback device (robot must select a Feedback device, or rely on default setting of Quadrature Encoder).
- Integrated Sensor (Talon FX).
- Magnet position and strength (CANCoder).

Tip: In LabVIEW, these signals can all be obtained from the “Get” VI from the motor controller’s sub-palette. Choose the type of signals desired from the VI’s drop-down menu.

2.19.7 Limit Switches

Talon SRX and Victor SPX have limit features that will auto-neutral the motor output if a limit switch activates. **Talon SRX** in particular can automatically do this **when limit switches are connected via the Gadgeteer feedback port**.

An “out of the box” Talon will **default with the limit switch setting of “Normally Open”** for both forward and reverse. This means that motor drive is allowed when a limit switch input is not closed (i.e. not connected to ground). When a limit switch input is closed (is connected to ground) the Talon SRX will disable motor drive and individually blink both LEDs red in the direction of the fault (red blink pattern will move towards the M+/white wire for positive limit fault, and towards M-/green wire for negative limit fault).

Since an “out of the box” Talon will likely not be connected to limit switches (at least not initially) and because limit switch inputs are internally pulled high (i.e. the switch is open), the limit switch feature is default to “normally open”. This ensures an “out of the box” Talon will drive even if no limit switches are connected.

For more information on Limit Switch wiring/setup, see the Talon SRX User’s Guide.

Forward Limit Switch Mode	Limit Switch NO pin	Limit Switch NC pin	Limit Switch COM pin	Motor Drive Switch open Fwd. throttle	Motor Drive Switch closed Fwd. throttle	*Voltage (Switch Open)	*Voltage (Switch Closed)
Normally Open	pin4	N.A.	pin10	Y	N	~2.5V	0 V
Normally Closed	N.A.	pin4	pin10	N	Y	0 V	~2.5V
Disabled	N.A.	N.A.	N.A.	Y	Y	N.A.	N.A.
Reverse Limit Switch Mode	Limit Switch NO pin	Limit Switch NC pin	Limit Switch COM pin	Motor Drive Switch open Rev. throttle	Motor Drive Switch closed Rev. throttle	*Voltage (Switch Open)	*Voltage (Switch Closed)
Normally Open	pin8	N.A.	pin10	Y	N	~2.5V	0 V
Normally Closed	N.A.	pin8	pin10	N	Y	0 V	~2.5V
Disabled	N.A.	N.A.	N.A.	Y	Y	N.A.	N.A.
*Measured voltage at the Talon SRX Limit Switch Input pin.							
Limit Switch Input Forward Input - pin4 on Talon SRX							
Limit Switch Input Reverse Input - pin8 on Talon SRX							
Limit Switch Ground - pin10 on Talon SRX							

Limit switch features can be disabled or changed to “Normally Closed” in Tuner and in API.

Note: When the source is set to Gadgeteer, the “Device ID” field is ignored. This config is used for **remote limit switches** (see next section).

Confirm the limit switches are functional by applying a **weak positive motor output** while tripping the forward limit switch.

Note: The motor does not have to be physically connected to the motor-controller if tester can artificially assert physical limit switch.

```

/* Configured forward and reverse limit switch of Talon to be from a feedback
↪connector and be normally open */
Hardware.leftTalonMaster.configForwardLimitSwitchSource(LimitSwitchSource.
↪FeedbackConnector, LimitSwitchNormal.NormallyOpen, 0);
Hardware.leftTalonMaster.configReverseLimitSwitchSource(LimitSwitchSource.
↪FeedbackConnector, LimitSwitchNormal.NormallyOpen, 0);

```

Limit Switch Override Enable

The enable state of the limit switches can be overridden in software. This can be called at any time to enable or disable both limit switches.

Generally you should call this instead of a config if you want to dynamically change whether you are using the limit switch or not inside a loop. This value is not persistent across power cycles.

```
/* Limit switches are forced disabled on Talon and forced enabled on Victor */
Hardware.leftTalonMaster.overrideLimitSwitchesEnable(false);
Hardware.rightVictorMaster.overrideLimitSwitchesEnable(true);;
```

Limit Switch As Digital Inputs

Limit switches can also be treated as digital inputs. This is done in Java/C++ by using the `isFwdLimitSwitchClosed` & `isRevLimitSwitchClosed` method.

```
_talon.getSensorCollection().isFwdLimitSwitchClosed();
_talon.getSensorCollection().isRevLimitSwitchClosed();
```

Note: The sensor being closed returns true in all cases, and the sensor being open returns false in all cases, regardless of normally open/normally closed setting. This ensures there is no ambiguity in the function name.

Remote Limit Switches

A Talon SRX or Victor SPX can use a remote sensor as the limit switch (such as another Talon SRX or CANifier).

Change the Limit Forward/Reverse Source to Remote Talon or Remote CANifier. Then config the Limit Forward/Reverse Device ID for the remote Talon or CANifier.

```
/* Configured forward and reverse limit switch of a Victor to be from a Remote Talon_
↳SRX with the ID of 3 and normally closed */
Hardware.rightVictorMaster.configForwardLimitSwitchSource(RemoteLimitSwitchSource.
↳RemoteTalonSRX, LimitSwitchNormal.NormallyClosed, 3, 0);
Hardware.rightVictorMaster.configReverseLimitSwitchSource(RemoteLimitSwitchSource.
↳RemoteTalonSRX, LimitSwitchNormal.NormallyClosed, 3, 0);
```

Use Self-test Snapshot on the motor-driving motor controller to confirm limit switches are interpreted correctly. If they are not correct, then Self-test Snapshot the remote device to determine the issue.

2.19.8 Soft Limits

Soft limits can be used to disable motor drive when the “Sensor Position” is outside of a specified range. Forward throttle will be disabled if the “Sensor Position” is greater than the Forward Soft Limit. Reverse throttle will be disabled if the “Sensor Position” is less than the Reverse Soft Limit. The respective Soft Limit Enable must be enabled for this feature to take effect.

```
/* Talon configured to have soft limits 10000 native units in either direction and enabled */
rightMaster.configForwardSoftLimitThreshold(10000, 0);
rightMaster.configReverseSoftLimitThreshold(-10000, 0);
rightMaster.configForwardSoftLimitEnable(true, 0);
rightMaster.configReverseSoftLimitEnable(true, 0);
```

The settings can be set and confirmed in Phoenix Tuner

2.20 Bring Up: Talon FX/SRX Sensors

This section is dedicated to validating any rotary sensor attached to the Talon SRX and the integrated sensor on the Talon FX. Generally attaching a sensor is necessary for:

- Close-Loop control modes (Position, MotionMagic, Velocity, MotionProfile)
- Soft limits (auto neutral motor if out of range)

2.20.1 Sensor Options

Many feedback interfaces are supported. The complete list is below.

Talon FX Integrated Sensor

The Talon FX has a sensor integrated into the controller. This is necessary for the brushless commutation and allows the user to use the Talon FX with a high resolution sensor without attaching any extra hardware.

In order to verify the Integrated Sensor is working, select the Talon FX in the dropdown.

And take a self-test snapshot of the Talon FX. Focus on the integrated sensor section of the snapshot and verify that rotating the shaft results in a change of position.

The screenshot shows the 'Self-Test Snapshot' window in the Phoenix software. The window has a yellow title bar and a blue border. The main content area is white and displays text-based configuration and status information. A green rectangular box highlights the 'Integrated Sensor' section, which includes position, velocity, and absolute position data. At the bottom of the window, there are three buttons: 'Self-Test Snapshot', 'Copy To Clipboard', and 'Blink / Clear Faults'. The status bar at the very bottom shows 'Self-Test Snapshot' and 'CAN Devices'.

Self-Test Snapshot CAN Devices

CANCoder

CANCoder is a great sensor to use for applications that require an absolute measurement of a mechanism or would otherwise require a long wire run back to a Talon SRX, CANifier, RIO, etc. If you are using a CANCoder, look at the [Bring Up: CANCoder](#) document.

Talon SRX External Ribbon Cabled Sensors

There are many external sensors that are compatible with the Talon SRX in order to utilize its closed-loop functionality or read inside your robot code.

Quadrature

The Talon directly supports quadrature sensors. The decoding is done in 4x mode (every edge on A and B are counted). This is available via the Gadgeteer feedback port.

Tip: Quadrature resets to 0 on power boot.

To verify your quadrature sensor is properly connected to the Talon SRX, select it in the dropdown and take a self-test snapshot of the Talon. Notice the Quadrature section displays all the relevant information about the quadrature sensor.

Analog (Potentiometer or Encoder)

Analog feedback sensors are sensors that provide a variable voltage to represent position. Some devices (such as the MA3 US Digital encoder) are continuous and wrap around from 3.3V back to 0V. In such cases the overwrap is tracked, and Talon continues counting 1023 => 1024.

This feature can be disabled by setting the config via API or Tuner.

To check that the analog sensor is working, select your Talon in the drop down and take a self-test snapshot. The Analog section of the snapshot displays all relevant information regarding your analog sensor.

Tip: Analog should read ~100 units if floating. If an analog sensor is meant to be in-circuit, recheck sensor signal/power/harness/etc.

Cross The Road Electronics Magnetic Encoder (Absolute and Relative)

The CTRE Magnetic Encoder is actually two sensor interfaces packaged into one (pulse width and quadrature encoder). Therefore the sensor provides two modes of use: absolute and relative. Each mode provides 4096 units per rotation.

Tip: Inspect the ribbon cable for any frayed or damaged sections.

Tip: Confirm the green LED. When using Versa-Planetary Sensor Slice, orange LED is acceptable.

Warning: When using a contactless sensor on a rolling mechanism (shooter / roller / intake), care should be taken to ensure spinning mechanism is electrically common to the remainder of the robot chassis. Otherwise ESD strikes can occur between mechanism and the contactless sensor (due to its proximity to the mechanism).

The advantage of absolute mode is having a solid reference to where a mechanism is without re-tare-ing or re-zero-ing the robot. The advantage of the relative mode is the faster update rate. However both values can be read/written at the same time. So a combined strategy of seeding the relative position based on the absolute position can be used to benefit from the higher sampling rate of the relative mode and still have an absolute sensor position.

Parameter	Absolute Mode	Relative Mode
Update rate (period)	4 ms	100 us
Max RPM	7,500 RPM	15,000 RPM
Accuracy	12 bits (4096 units per rotation)	12 bits (4096 units per rotation)
Software API	Select Pulse Width	Select Quadrature

In circumstances where the absolute pulse width wraps from one extremity to the other (due to overflow), the Talon continues counting 4095 => 4096.

This feature can be disabled by setting the config via API or Tuner.

In order to test that the Mag Encoder is connected properly to the Talon SRX and verify that it is working, you should first select the Talon SRX using the drop down, and take a self-test snapshot of the Talon. The Mag Encoder uses both Quadrature and Pulse Width, so the relevant information for the Mag Encoder will be in both of those sections in the self-test.

```

2.20.2 Software-Select Sensor

Once you have decided what sensor you are going to use, you have to select that sensor in the software.

Note: It is imperative that this step is done regardless of if you wish to use the device's closed-looping features or not.

This step is done for a number of reasons:

- It allows the device to use the selected sensor in its closed looping.
- It allows the user to use the `getSelected*` API
 - This is updated faster than the sensor-specific gets inside the Sensor Collection.
 - This obeys the sensor phase that's been set.
 - This obeys any sensor coefficient that's been configured.

Selecting the sensor is done with either Phoenix API or Tuner. In order to select the sensor using Tuner, choose your device in the drop down, access the Config Tab, and select the sensor you are using.

Note: The selected "Feedback Device" defaults to *Quadrature Encoder* for Talon SRX, *None* for Victor SPX, and *Integrated Sensor* for Talon FX.

To select it using Phoenix API, call `configSelectedFeedbackSensor`.

```
_tal.configSelectedFeedbackSensor(FeedbackDevice.CTRE_MagEncoder_Relative, 0, 10);
```

Verify the sensor has been selected by taking another self-test snapshot of the device and confirming PID0's Feedback is the selected sensor

Because the sensor is now “selected”, turn on the plot and hand rotate sensor back and forth. Disable plot to pause after capturing several seconds.

Checks:

- Focus the velocity and position curves and look for any discontinuities in the plot.
- Shake the sensor harness while hand-turning mechanism.
- This is also a good opportunity to confirm the resolution of the sensor.

2.20.3 Sensor Check - With Motor Drive

In this step we will attempt to drive motor while monitoring sensor value. Motor controller can be controlled using Control-tab (see previous relevant section) or controlled from robot application via Phoenix API (see previous relevant section).

Sensor Phase

Sensor phase describes the relationship between the motor output direction (positive vs negative) and sensor velocity (positive vs negative). For soft-limits and closed-loop features to function correctly, the sensor measurement and motor output must be “in-phase”.

Note: Talon FX automatically phases your sensor for you. It will always be correct, provided you use the `getSelected*` API and have configured the selected feedback type to be integrated sensor.

Note: Sensor phase is **not** the same as sensor direction. When `SetInverted` is called on a motor controller, the values reported by the selected sensor are **also inverted**. As a result, changing the `SetInverted` input does **not** require changing the sensor phase.

Measure Sensor Phase

Take another measurement using your preferred control method and check the sensor phase using any of the following methods.

Here we sweep the motor output forward and reverse. Notice that sensor velocity (green) and motor output (blue) are out of phase.

In this capture we use the Self-test Snapshot to observe the motor output and selected (PID0) sensor velocity are signed in opposite directions. Additionally the Talon SRX noticed this and reported a live fault of “Sensor Out of Phase”.

Note: Talon SRX will check sensor direction versus output direction once motor output and velocity exceeds a minimum threshold.

Adjust Sensor Phase

If the sensor is out of phase with the motor drive, you can use any method below to align them:

- **Recommended:** Use **setSensorPhase** routine/VI to adjust the sensor phase. If already called, toggle the input so that the sensor phase becomes aligned with motor output.
- Exchange/flip the green/white motor leads. **This is generally not recommended** as this makes maintaining motor controller orientation across multiple robots difficult (practice versus competition).

Warning: Do not use **setInverted** to correct sensor orientation with respect to motor output. **setInverted** synchronously inverts both signals, ensuring that sensor phase

is maintained. **This is a feature** that allows you to choose what direction is considered positive without breaking closed-looping features.

Confirm Sensor Phase using API

The next test is to control the motor controller using Phoenix API on the robot controller. This is ultimately how you will leverage the motor controller in competition.

```
package frc.robot;

import com.ctre.phoenix.motorcontrol.*;
import com.ctre.phoenix.motorcontrol.can.*;
import edu.wpi.first.wpilibj.*;

public class Robot extends TimedRobot {
    TalonSRX _talon = new TalonSRX(0); /* make a Talon */
    Joystick _joystick = new Joystick(0); /* make a joystick */
    Faults _faults = new Faults(); /* temp to fill with latest faults */

    @Override
    public void teleopInit() {
        /* factory default values */
        _talon.configFactoryDefault();

        /*
         * choose whatever you want so "positive" values moves mechanism forward,
         * upwards, outward, etc.
         *
         * Note that you can set this to whatever you want, but this will not fix motor
         * output direction vs sensor direction.
         */
        _talon.setInverted(false);

        /*
         * flip value so that motor output and sensor velocity are the same polarity. Do
         * this before closed-looping
         */
        _talon.setSensorPhase(false); // <<<<<< Adjust this
    }

    @Override
    public void teleopPeriodic() {
        double xSpeed = _joystick.getRawAxis(1) * -1; // make forward stick positive

        /* update motor controller */
        _talon.set(ControlMode.PercentOutput, xSpeed);
        /* check our live faults */
        _talon.getFaults(_faults);
        /* hold down btn1 to print stick values */
        if (_joystick.getRawButton(1)) {
            System.out.println("Sensor Vel:" + _talon.getSelectedSensorVelocity());
            System.out.println("Sensor Pos:" + _talon.getSelectedSensorPosition());
            System.out.println("Out %" + _talon.getMotorOutputPercent());
            System.out.println("Out Of Phase:" + _faults.SensorOutOfPhase);
        }
    }
}
```

(continues on next page)

(continued from previous page)

```
}  
}  
}
```

Confirm sensor velocity is in phase with motor output using any of the methods documented above.

Below is an example screenshot of a successfully phased sensor and motor output. Both are negative (good).

The screenshot shows the FRC Message Console with a list of messages. The messages are as follows:

```
Out Of Phase:true  
Sensor Vel:-3976  
Sensor Pos:780351  
Out %-1.0  
Out Of Phase:false  
Sensor Vel:-3974  
Sensor Pos:772394  
Out %-1.0  
Out Of Phase:false  
Warning 44000 DS Disable Driver Station  
Default disabledInit() method... Overload me!
```

Below is an example screenshot of a successfully phased sensor and motor output. Both are negative (in green).

Note: The natural sensor measurement (purple) under Quad is opposite of the Selected sensor value. This is proof-positive that `setSensorPhase(true)` was used to adjust the sensor phase to better match the motor voltage direction.

What if the sensor Phase is already correct?

The recommendation is to **always call setSensorPhase routine/VI**. If the phase is naturally correct, then pass false. The reasons to do this are:

- During competition, you may find the pit-crew / repair-team wired a replacement motor/harness incorrectly and must resolve this with a “quick software fix”.
- During competition, you may find the pit-crew / repair-team wired a replacement sensor/harness incorrectly and must resolve this with a “quick software fix”.
- This provides the means of changing the sensor phase to the “wrong value” during hardware-bring up, so you can demonstrate to other team members what an out of phase sensor looks like in your telemetry.

2.20.4 Confirm Sensor Resolution/Velocity

After correcting the sensor phase, the next step is to confirm sensor resolution matches your expectations. This is an important step in sensor validation.

Listed below are the typical sensor resolutions for common sensors. Lookup your sensor type and note the expected resolution. Call this kSensorUnitsPerRotation.

Sensor Resolution

Sensor Type	Units per rotation
Quadrature Encoder : US Digital 1024 CPR	4096 (Talon SRX / CANifer counts every edge)
CTRE Magnetic Encoder (relative/quadrature)	4096
CTRE Magnetic Encoder (absolute/pulse width)	4096
Talon FX Integrated Sensor	2048
CANCoder	4096
Any pulse width encoded position	4096 represents 100% duty cycle
AndyMark CIMcoder	80 (because 20 pulses => 80 edges)
Analog	1024

Note: Sensor are typically reported in the raw sensor units to ensure all of the available sensor resolution is utilized. However future releases will allow user to choose how sensor position is interpreted (for example: degrees, radians, inches, legacy raw units, etc.). Users can review the CANCoder API as a reference to how this will work.

Lookup the kMaxRPM of your motor. This will be advertised as the free-speed or max-velocity of your motor.

Determine if your mechanism has a gear-ratio between the motor and your sensor. Typically this is a reduction, meaning that there are several motor rotations per single sensor rotation. Call this kGearRatio.

Calculate the expect peak sensor velocity (sensor units per 100ms) as:

$$(kMaxRPM / 600) * (kSensorUnitsPerRotation / kGearRatio)$$

Knowing the maximum possible sensor velocity, compare this against the sensor velocity report in any of the following:

- Self-test Snapshot under selected sensor (PID0).
- `getSelectedSensorVelocity()` API
- Tuner plotter sensor velocity

You will likely find your ideal value is greater than your measured value due to load. In the case of testing a drive train, it is recommend to place robot on a tote/crate so that wheels can spin free.

If your mechanism does not allow for full motor output due to its design, choose a slower duty cycle and scale by the expected velocity.

2.20.5 Setting Sensor Position

Depending on the sensor selected, the user can modify the “Sensor Position”. This is particularly useful when using a Quadrature Encoder (or any relative sensor) which needs to be “zeroed” or “home-ed” when the robot is in a known position.

Auto Clear Position using Index Pin Or Limit Switches

In addition to manually changing the sensor position, the Talon SRX supports automatically resetting the Selected Sensor Position to zero whenever a digital edge is detected.

This can be activated via config API or config tab in Tuner.

Clear Pos event can be triggered by:

- Falling edge on Forward Limit (pin 4)
- Falling edge on Reverse Limit (pin 8)
- Rising edge on Quadrature Index (pin 9)

```
talon.configClearPositionOnLimitF(true, timeoutMs);
talon.configClearPositionOnLimitR(true, timeoutMs);
talon.configClearPositionOnQuadIdx(true, timeoutMs);
```

Self-test Snapshot can also be used to confirm the enabling of auto zero features.

2.20.6 Velocity Measurement Filter

The Talon SRX measures the velocity of all supported sensor types as well as the current position. Every 1ms a velocity sample is measured and inserted into a rolling average.

The velocity sample is measured as the change in position at the time-of-sample versus the position sampled 100ms-prior-to-time-of-sample. The rolling average is sized for 64 samples. Though these settings can be modified, the (100ms, 64 samples) parameters are default.

Changing Velocity Measurement Parameters.

The two configs for the Talon Velocity Measurement are:

- Sample Period (Default 100ms)
- Rolling Average Window Size (Default 64 samples).

Each can be modified through programming API, and through Tuner.

Note: When the sample period is reduced, the units of the native velocity measurement is still change-in-position-per-100ms. In other words, the measurement is up-scaled to normalize the units. Additionally, a velocity sample is always inserted every 1ms regardless of setting selection.

Note: The Velocity Measurement Sample Period is selected from a fixed list of pre-supported sampling periods [1, 5, 10, 20, 25, 50, 100(default)] milliseconds.

Note: The Velocity Measurement Rolling Average Window is selected from a fixed list of pre-supported sample counts: [1, 2, 4, 8, 16, 32, 64(default)]. If an alternative value is passed into the API, the firmware will truncate to the nearest supported value.

Recommended Procedure

The general recommended procedure is to first set these two parameters to the minimal value of '1' (Measure change in position per 1ms, and no rolling average). Then plot the measured velocity while manually driving the Talon SRX(s) with a joystick/gamepad. Sweep the motor output to cover the expected range that the sensor will be expected to cover.

Unless the sensor velocity is considerably fast (hundreds of sensor units per sampling period) the measurement will be very coarse (visual stair-stepping as the motor output is increased). Increase the sampling period until the measured velocity is sufficiently granular.

At this point the sensor velocity will have minimal stair-stepping (good) but will be quite noisy. Increase the rolling average window until the velocity plot is sufficiently smooth, but still responsive enough to meet the timing requirements of the mechanism.

2.20.7 Next Steps

Additionally if you need to use **WPI features** such as the **drivetrain classes**, or **motor safety**, move on to [WPI/NI Software Integration](#).

Now that you have a reliable sensor, you can setup a closed-loop. This is for use cases where you want your mechanism to automatically **move towards a target position**, or **hold a target velocity**. This is covered in [Motor Controller Closed Loop](#).

2.21 Bring Up: Remote Sensors

This section provides direction for **configuring and validating remote sensor** setups. The remote sensor filter feature of the Talon SRX/Victor SPX allows for the processing of sensor values provided from other *remote* CAN bus devices. In other words, a Talon SRX or Victor SPX can **execute closed-loop modes with sensor values sourced by other Talons, CANifiers, or Pigeon IMUs** on the same CAN-bus.

This is useful for two general reasons:

- Victor SPX does not have a Gadgeteer feedback port, so it must rely on *remote* sensors for sensor data.
- Situations where the sensor is physically located too far from the motor controller for reliable/robust wiring.

As a result, the remote sensor feature enables:

- Close-Loop control modes (Position, MotionMagic, Velocity, MotionProfile) when the sensor **cannot be directly connected to the motor controller**.
- Soft limits (auto neutral motor if out of range) when the sensor **cannot be directly connected to the motor controller**.
- **Auxiliary PID1 Closed-Loop** (differential mechanisms) that **requires more than one sensor source** (including MotionProfileArc, and all other Closed-Loop control modes).

Note: To use Pigeon IMU as a remote sensor over gadgeteer ribbon cable you must use Pigeon firmware 4.13 or higher. There is a bug that prevents Pigeon from appearing as a remote sensor in some cases over gadgeteer ribbon cable that has been fixed in 4.13

2.21.1 Bring up the sensor on the remote CTRE CAN device

In order to use remote sensors, **the sensor must first be validated by the device wired to the sensor. If the sensor is not reliable at the remote device, then it will not function when utilized remotely.**

This is done by following the sensor bring up instructions for that particular device type:

Warning: In order for a motor controller to use another Talon sensor as a remote source, that Talon must have the correct sensor type selected. In other words, if Victor X is going to use Talon Y's analog sensor, Talon Y must have a *selected sensor type* set to *analog*.

Warning: Remote sensors accessed by a Talon FX (Falcon 500) must have a CAN ID of 15 or less. See errata [Talon FX Remote Filter Device ID Must be 15 or Less](#) for more details.

Note: When PigeonIMU is selected as a remote sensor, the closed loop uses the Pigeon's **native units** (8192 units per rotation). This can be changed by configuring a sensor coefficient for the closed loop, see [Closed-Loop Configurations](#).

2.21.2 Filter configuration

Inside Phoenix Tuner select the motor controller that will be utilizing the remote sensor data and go to the config tab. Inside the tab go to the remote sensor portion and expand it, where you will see filter sources and filter device IDs.

Select the dropdown for filter source 0, and you will see a list of the possible sources of a remote sensor

Select the option that you wish to use, for the purpose of this example we will select a RemoteSRX_SelectedSensor that has configured a quadrature encoder, but any of these will work.

Warning: When selecting a Pigeon IMU data, there are **two** separate options for Pigeon - one for connection via CAN bus and one for connection to a remote Talon via ribbon cable.

As well as this, select Filter 0 Device ID and set it to the CAN device ID of the remote sensor. Press save, making sure the text goes from bold to non-bold.

Filter 0 Device ID	2
Filter 0 Source	RemoteSRX_SelectedSensor

Note: If the filter source is a RemoteGadgeteerPigeon type, the filter Device ID should be the device ID of the remote Talon SRX hosting the Pigeon IMU.

2.21.3 Sensor Check - No Motor Drive

After having the filter configured, it is important to check that it is behaving properly. Under the closed loop section of the configs, configure PID 0 Primary Feedback Sensor to be Remote Sensor 0 and press save.

And perform a Self-test Snapshot to make sure the configuration took place.

```

Tip: If something is not behaving correctly, double check the sensor setup for that device. If the sensor setup behaves correctly, the error is somewhere in the filter configuration

2.21.4 Sensor Check - With Motor Drive

See *Sensor Check – With Motor Drive* for the guide on checking the sensor with motor drive.

2.21.5 Remote Features Check

With the sensor being properly configured, now we can test the remote features. A simple way of testing this is by configuring soft limits and checking to make sure those soft limits are upheld by the controller

First, we configure the soft limits on the motor controller so that they're enabled and have values for the forward and reverse limits

Software Limit Switches	
Forward Soft Limit Enable	True
Reverse Soft Limit Enable	True
Soft Limit Forward Value	500
Soft Limit Reverse Value	-500

Then, we drive the motor to one of the limits. It will probably overshoot a bit, but the important piece is that the motor controller's output is neutral after hitting the soft limit, which we can check in the Self-test Snapshot and looking at the faults.

```

2.21.6 Next Steps

Now that the remote sensor is configured, it can be used for *Motor Controller Closed Loop* or *Bring Up: Differential Sensors*.

2.22 Bring Up: Differential Sensors

This section is dedicated to validating differential sensors for any CTRE motor controller. Generally a differential sensor is necessary for:

- Closed-Loop control modes (Position, MotionMagic, Velocity, MotionProfile) when the mechanism has more than one sensor attached.
- Auxiliary Closed-Loop control modes (MotionProfileArc, and all other Closed-Loop control modes) for mechanisms that require a differential component (Such as an elevator where the two sides are not linked mechanically, or a drive train).

2.22.1 Bring up Sensors as Remote/Local sensors

In order to use differential sensors, you must bring up all relevant sensors on their local controller devices.

See relevant BringUp sections below:

- *Initial Hardware Testing*
- *Bring Up: CAN Bus*
- *Bring Up: PCM*
- *Bring Up: PDP*
- *Bring Up: Pigeon IMU*
- *Bring Up: CANifier*
- *Bring Up: Talon FX/SRX and Victor SPX*
- *Bring Up: Talon FX/SRX Sensors*

After each sensor is brought up on its local device, all remote sensors should be configured as a remote filter on the master device. See *Bring Up: Remote Sensors*.

2.22.2 Configure sensors as Sum/Diff terms

Once the sensors are brought up and checked, we can move on to configuring them as the sum difference (diff) terms.

The sum of two sensors is used primarily to calculate the overall movement of the mechanism. For example, in the case of a differential lift the sum of two sensors is used to calculate the height of the lift.

Tip: When using the sum of two sensors for total movement, you can also set the Feedback Coefficient to 0.5 on order to scale the value back to the original units.

The difference of two sensors, however, is mostly used to calculate the differential portion of the mechanism. For example, for a differential lift the difference represents how level the lift is.

The sum and diff terms will almost always be the same sensors, and will almost always be a local sensor and a remote sensor (or two remote sensors).

```

/* Below shows setting the member variables of a motor controller Config object. */
/* Remote Sensor 0 is the other talon's quadrature encoder */
remoteFilter0.remoteSensorSource = RemoteSensorSource::RemoteSensorSource_TalonSRX_
    SelectedSensor;
remoteFilter0.remoteSensorDeviceID = otherTalon->GetDeviceID();

/* Configure sensor sum to be this quad encoder and the other talon's encoder */
sum0Term = FeedbackDevice::QuadEncoder;
sum1Term = FeedbackDevice::RemoteSensor0;

```

2.22.3 Auxiliary PID Polarity

The Auxiliary PID Polarity flag configures whether the master motor controller uses the addition of the two PID's and the auxiliary follower uses the subtraction, or if the master uses the subtraction and the auxiliary follower uses the addition.

Setting this to false will cause the master/follower pair to behave like this:

- Master Motor Controller Output = $PID[0] + PID[1]$
- Auxiliary Follower Output = $PID[0] - PID[1]$

Setting this to true will cause the master/follower pair to behave like this:

- Master Motor Controller Output = $PID[0] - PID[1]$
- Auxiliary Follower Output = $PID[0] + PID[1]$

2.22.4 Using the differential sensor setup

This is covered in *Motor Controller Closed Loop*

2.23 WPI/NI Software Integration

The stock software frameworks in the FRC control system has several features used by teams. To leverage these features, the C++ /Java Phoenix API has six additional classes:

- WPI_TalonFX
- WPI_TalonSRX
- WPI_VictorSPX
- WPI_CANCoder

- WPI_PigeonIMU
- WPI_Pigeon2

The first three are wrappers for the Talon FX/SRX and Victor SPX, that provide:

- LiveWindow support
- Motor Safety features
- Compatibility with DriveTrain classes

All six classes also provide support for the WPILib simulation GUI.

2.23.1 C++ / Java Drive Train classes

To leverage the Drive Train classes in WPILib:

- Create your motor controller objects like normal.
- Create the Drive object like normal.
- Call `setRightSideInverted(false)` so that when moving forward, positive output is applied to left and right.
- Adjust `setInverted()` so that motors cause robot to drive straight forward when stick is forward.

```
package frc.robot;

import com.ctre.phoenix.motorcontrol.can.*;
import edu.wpi.first.wpilibj.*;
import edu.wpi.first.wpilibj.drive.*;

public class Robot extends TimedRobot {
    WPI_TalonSRX _talonL = new WPI_TalonSRX(1);
    WPI_TalonSRX _talonR = new WPI_TalonSRX(0);
    DifferentialDrive _drive = new DifferentialDrive(_talonL, _talonR);
    Joystick _joystick = new Joystick(0);

    @Override
    public void teleopInit() {
        /* factory default values */
        _talonL.configFactoryDefault();
        _talonR.configFactoryDefault();

        /* flip values so robot moves forward when stick-forward/LEDs-green */
        _talonL.setInverted(false); // <<<<< Adjust this
        _talonR.setInverted(true); // <<<<< Adjust this

        /*
         * WPI drivetrain classes defaultly assume left and right are opposite. call
         * this so we can apply + to both sides when moving forward. DO NOT CHANGE
         */
        _drive.setRightSideInverted(false);
    }

    @Override
    public void teleopPeriodic() {
        double xSpeed = _joystick.getRawAxis(1) * -1; // make forward stick positive
    }
}
```

(continues on next page)

(continued from previous page)

```
double zRotation = _joystick.getRawAxis(2); // WPI Drivetrain uses positive=>
↳right

_drive.arcadeDrive(xSpeed, zRotation);

/* hold down btn1 to print stick values */
if (_joystick.getRawButton(1)) {
    System.out.println("xSpeed:" + xSpeed + "    zRotation:" + zRotation);
}
}
```

Tip: It is advantageous to setup Talon / Victors in this fashion so that positive (green) represents forward motion. This makes integrating the other control modes into your drive train simpler.

2.23.2 C++ / Java Motor Safety Feature

The Java classes WPI_TalonFX, WPI_TalonSRX, and WPI_VictorSPX all implement the motor safety interface.

The C++ classes WPI_TalonFX, WPI_TalonSRX, and WPI_VictorSPX do not inherit the motor safety abstract class, but they do implement the exact same routines. This means the same routines can be called on the Phoenix WPI objects.

2.24 Simulation

2.24.1 Supported Devices

Currently, the following devices are supported in simulation:

- Talon SRX
- Talon FX
- Victor SPX
- CANCoder
- Pigeon IMU
- Pigeon 2.0

Warning: Multiple CAN buses using the CANivore API is not supported at this time. All CAN devices will **appear on the same CAN bus**. If you wish to run your robot code in simulation, ensure devices have **unique IDs across CAN buses**.

2.24.2 Simulation API

Each supported device has a `SimCollection` object to manage I/O with the simulation model. The object can be retrieved by calling `getSimCollection()` on an instance of a device.

```
TalonFX fx = new TalonFX(0);
TalonFXSimCollection fx_sim = fx.getSimCollection();
```

Tip: For example usage of the `SimCollection` API, check out our [examples](#) that support simulation, such as our [differential drive simulation example](#).

Note: Simulating non-FRC applications (not using `WPI_*` classes) will require calling `Unmanaged.feedEnable(100)`; to enable simulated actuators.

Note: To view simulated devices in the WPILib simulation GUI, use the `WPI_*` class extensions.

2.24.3 Simulating Sensors

CTRE device simulation reflects what the physical device would see in normal hardware operation. This does not always reflect the behavior of our regular device APIs.

As an example, when `setInverted(true)` is called on a motor controller, the following values are all inverted in the regular device API:

- input to `set()`
- output of `getMotorOutputPercent()`
- output of `getMotorOutputVoltage()`
- input to `setSelectedSensorPosition()`
- output of `getSelectedSensor*()`

However, the `SimCollection` I/O represents what the physical motor controller sees. For example, `getMotorOutputLeadVoltage()` returns the voltage you would read across the motor output leads with a voltmeter. If the motor is inverted, the voltage measured will be inverted from what is seen in the regular device API.

Therefore, in the `SimCollection` API, none of the following values will be inverted:

- output of `SimCollection.getMotorOutputLeadVoltage()`
- input to `SimCollection.set*Position()`
- input to `SimCollection.add(Quadrature/IntegratedSensor)Position()`
- input to `SimCollection.set*Velocity()`

It is important to take this into account to avoid unexpected behavior. For example, using the output of `getMotorOutputVoltage()` to determine the input of `SimCollection.set*Velocity()` will result in the sensor values being inverted in the API. However, using the output of `SimCollection.getMotorOutputLeadVoltage()` will result in the expected behavior.

2.24.4 “Raw” Quadrature/Integrated Sensor Position

The quadrature sensor on the Talon SRX and the integrated sensor on the Talon FX have a unique problem. Users can set the position of the sensor through the regular device API using `setSelectedSensorPosition()` and `SensorCollection.set(Quadrature/IntegratedSensor)Position()`. However, the user simulation model does not know about these calls. Our solution is to separate the encoder values seen in the regular device API from the simulated encoder values. We call this separate simulated encoder position the “raw” position.

When the raw position of the quadrature or integrated sensor is set in the `SimCollection` API, the simulated device takes the difference between the new raw position and the previous raw position. It then adds that difference to the actual sensor position reported to the user. As a result, the user simulation model does **not** have to worry about user calls to `setSelectedSensorPosition()`.

2.25 Motor Controller Closed Loop

2.25.1 Primer on Closed-loop

Talon SRX and Victor SPX supports a variety of closed-loop modes including position closed-loop, velocity closed-loop, Motion Profiling, and Motion Magic. Talon SRX additionally supports current closed-loop.

Note: All closed-loop modes update every 1ms (1000Hz) unless configured otherwise.

Tip: While tuning the closed-loop, use the Tuner configuration tab to quickly change the gains “on the fly”. Once the PID is stable, set the gain values in code so that Talons can be swapped/replaced easily.

Regardless of which closed-loop control mode is used, the following statements apply:

- Current limit and voltage compensation selections are honored (just like in open-loop PercentOutput mode)
- “Ramping” can be configured using `configClosedloopRamp` (routine or VI)
- All other open-loop features are honored during closed loop (neutral mode, peaks, nominal outputs, etc.).
- Closed Loop controller will pull closed-loop gain/setting information from a selected slot. There are four slots to choose from (for gain-scheduling).
- PIDF controller takes in target and sensor position measurements in “raw” sensor units. This means a CTRE Mag Encoder will count 4096 units per rotation.
- PIDF controller takes in target and sensor velocity measurements in “raw” sensor units per 100ms.
- PIDF controller calculates the motor output such that, 1023 is interpreted as “full”. This means a closed loop error of 341 (sensor units) X kP of 3.0 will produce full motor output (1023).

Warning: Although the velocity kF config of the Talon-SRX/Victor-SPX assumes 1023 is full output, do not confuse this with the arbitrary feed-forward parameter of the Set routine/VI, which accepts a value within [-1,+1]

Below are descriptions for the various control modes.

Closed-Loop Control Modes

Position Closed-Loop Control Mode

The Position Closed-Loop control mode can be used to abruptly servo to and maintain a target position.

A simple strategy for setting up a closed loop is to zero out all Closed-Loop Control Parameters and start with the Proportional Gain.

For example if you want your mechanism to drive 50% throttle when the error is 4096 (one rotation when using CTRE Mag Encoder), then the calculated Proportional Gain would be $(0.50 \times 1023) / 4096 = \sim 0.125$.

Tune this until the sensed value is close to the target under typical load. Many prefer to simply double the P-gain until oscillations occur, then reduce accordingly.

If the mechanism accelerates too abruptly, Derivative Gain can be used to smooth the motion. Typically start with 10x to 100x of your current Proportional Gain. If application requires a controlled (smooth) deceleration towards the target, we strongly recommend motion-magic.

If the mechanism never quite reaches the target and increasing Integral Gain is viable, start with 1/100th of the Proportional Gain.

Current Closed-Loop Control Mode

The Talon's Closed-Loop logic can be used to approach a target current-draw. Target and sampled current is passed into the PIDF controller in milliamperes. However the robot API expresses the target current in amperes.

Note: Current Control Mode is separate from Current Limit.

Tip: A simple strategy for setting up a current-draw closed loop is to zero out all Closed-Loop Control Parameters and start with the Feed-Forward Gain. Tune this until the current-draw is close to the target under typical load. Then start increasing P gain so that the closed-loop will make up for the remaining error.

Warning: This feature is not available on Victor SPX.

Velocity Closed-Loop Control Mode

The Talon's Closed-Loop logic can be used to maintain a target velocity. Target and sampled velocity is passed into the equation in native sensor units per 100ms.

Tip: A simple strategy for setting up a closed loop is to zero out all Closed-Loop Control Parameters and start with the Feed-Forward Gain. Tune this until the sensed value is close to the target under typical load. Then start increasing P gain so that the closed-loop will make up for the remaining error.

Tip: Velocity Closed-Loop tuning is similar to Current Closed-Loop tuning in their use of feed-forward. Begin by measuring the sensor velocity while driving the Talon at a large throttle.

Motion Magic Control Mode

Motion Magic is a control mode for Talon SRX that provides the benefits of Motion Profiling without needing to generate motion profile trajectory points. When using Motion Magic, Talon SRX / Victor SPX will move to a set target position using a motion profile, while honoring the user specified acceleration, maximum velocity (cruise velocity), and optional S-Curve smoothing.

Tip: Motion Magic in firmware ≥ 4.17 (Talon SRX and Victor SPX) now supports an S-Curve parameter, allowing you to create a continuous velocity profile.

The benefits of this control mode over “simple” PID position closed-looping are:

- Control of the mechanism throughout the entire motion (as opposed to racing to the end target position).
- Control of the mechanism's inertia to ensure smooth transitions between set points.
- Improved repeatability despite changes in battery voltage.
- Improved repeatability despite changes in motor load.

After gain/settings are determined, the robot-application only needs to periodically set the target position.

There is no general requirement to “wait for the profile to finish”, however the robot application can poll the sensor position and determine when the motion is finished if need be.

Motion Magic functions by generating a trapezoidal/S-Curve velocity profile that does not exceed the specified acceleration or cruise velocity. This is done automatically as the Talon SRX / Victor SPX determines on-the-fly when to modify its velocity to accomplish this.

Note: If the remaining sensor distance to travel is small, the velocity may not reach cruise velocity as this would overshoot the target position. This is often referred to as a “triangle profile”.

Example Trapezoidal Motion Profile

If the S-Curve strength [0,8] is set to a nonzero value, the generated velocity profile is no longer trapezoidal, but instead is continuous (corner points are smoothed).

An S-Curve profile has the following advantages over a trapezoidal profile:

- Control over the Jerk of the mechanism.
- Reducing oscillation of the mechanism.
- Maneuver is more deliberate and reproducible.

Tip: The S-Curve feature, by its nature, will increase the amount of time a movement requires. This can be compensated for by decreasing the configured acceleration value.

Motion Magic utilizes the same PIDF parameters as Motion Profiling.

Three additional parameters need to be set in the Talon SRX- Acceleration, Cruise Velocity, and Acceleration Smoothing.

The Acceleration parameter controls acceleration and deacceleration rates during the beginning and end of the trapezoidal motion. The Cruise Velocity parameter controls the cruising (peak) velocity of the motion. The Acceleration smoothing parameter controls the “curve” of the velocity, a larger smoothing value will result in greater dampening of the acceleration.

Motion Profile Control Mode

Talon SRX and Victor SPX support other closed-loop modes that allow a “Robot Controller” to specify/select a target value to meet. The target can simply be the percent output motor drive, or a target current-draw. When used with a feedback sensor, the robot controller may also simply set the target position, or velocity to servo/maintain.

However, for advanced motion profiling, the Talon SRX / Victor SPX additionally supports a mode whereby the robot controller can *stream* a sequence of trajectory points to express an *entire motion profile*.

Each trajectory point holds the desired velocity, position, arbitrary feedforward, and time duration to honor said point until moving on to the next point. The point also holds targets for both the primary and auxiliary PID controller, allowing for differential control (drivetrain, differential mechanisms).

Alternatively, the trajectory points can be streamed into the motor controller *as the motor controller is executing the profile*, so long as the robot controller sends the trajectory points faster than the Talon consumes them. This also means that there is no practical limit to how long a profile can be.

Tip: Starting in 2019, the Talon and Victor will linearly interpolate targets between two buffer points every 1ms. This means you can send points with larger time durations, but still have a smooth continuous motion. This features default on.

What is the benefit? Leveraging the Motion Profile Control Mode in the Talon SRX has the following benefits:

- Direct control of the mechanism throughout the entire motion (as opposed to a single PID closed-loop which directly servos to the end target position).
- Accurate scheduling of the trajectory points that is not affected by the performance of the primary robot controller.
- Improved repeatability despite changes in battery voltage.
- Improved repeatability despite changes in motor load.
- Provides a method to synchronously gain-schedule.

Additionally, this mode could be used to schedule several position servos in advance with precise time outs. For example, one could map out a collection of positions and timeouts, then stream the array to the Talon SRX to execute them.

Motion Profile Arc Control Mode

Motion Profile Arc utilizes the Auxiliary Closed Loop features to profile the motion of not just *one* degree of freedom, but of *two*.

In the example of trying to profile the movement of the robot on a field, the primary PID can be used to ensure the robot is a specified distance (sum or average of both sides), and at the same time the Auxiliary PID can be used to ensure the robot is facing the right direction (difference of both sides or heading from a pigeon), allowing the robot to follow a spline.

The benefits of this are the same as for the Motion Profile control mode, and at the same time expands on the possibilities this can be used for.

Auxiliary Closed Loop PID[1]

Along with the above control modes, the Talon SRX / Victor SPX has the ability to run a second PID loop, called the auxiliary PID[1] loop. This is typically used in differential mechanisms where application must maintain two process variables (e.g. sum/average of two sensors, along with the difference or IMU heading).

When used, the motor controller will simultaneously calculate: - PID[0] + PID[1] (this is applied to the motor output) - PID[0] - PID[1] (this is sent to a follower)

Note: The follower Talon / Victor must have a followType of AuxOutput1. Use the follow routine/VI to accomplish this.

Note: The signage of the PID[1] term can be modified allowing the master Talon to subtract the term instead of adding it.

Note: In order to use Auxiliary Closed Loop, a remote sensor will need to have been configured for PID[0] or PID[1]. Look at [Bring Up: Remote Sensors](#) to see how to do this

Note: The Control Mode of Auxiliary Closed Loop is *always* position closed-loop.

Some example setups are provided below, with a step-by-step walkthrough provided after the PID tuning sections. See [Auxiliary Closed Loop PID\[1\] Walkthrough](#).

Example 1 - Differential Drivetrain

Consider the application of controlling the position of a drive train with Position Control Mode, given an encoder on the left and right side.

PID[0] will use the sum (or average if sensor coefficient is set to 0.5) of the left and right sensor to produce the *traveled robot distance*. Given a target distance, the PID[0] output will move the robot closer to the target distance. PID[1] will use the difference between the left and right sensor to produce the *robot heading*. Alternatively the Pigeon IMU can be used to remotely provide this. The PID[1] output will then maintain the robot's heading throughout the maneuver.

Note: If Velocity control mode is used, the aux PID[1] loop still uses the position value of its respective sensor source. This is convenient for controlling the robot-velocity while maintaining robot-heading.

Note: When using the Motion Magic control mode, the target for PID[1] is smoothed identically to PID[0], and both targets should be reached at approximately the same time.

Note: Sensor difference (and not sum) may represent the distance traveled depending on the signage of the sensors involved.

Example 2 - Lift Mechanism

Consider a lifting mechanism composed of two closed-loops (one for each side) and no mechanical linkage between them. In other words, the left and right side each have a unique motor controller and sensor. The goal in this circumstance is to closed-loop the elevation while keeping the left and right side reasonably synchronized.

This can be accomplished by using the sum of each side as the elevator height, and the difference as the level deviation between the left and right, which must be kept near zero.

Aux PID[1] can then be used to apply a corrective difference component (adding to one side and subtracting from the other) to maintain a synchronous left and right position, while employing Position/Velocity/Motion-Magic to the primary axis of control (the elevator height).

2.25.2 Sensor Preparation

Before invoking any of the closed loop modes, the following must be done:

- Complete the sensor bring up procedure to ensure sensor phase and general health.
- Record the maximum sensor velocity (position units per 100ms) at 100% motor output.
- Calculate an Arbitrary Feed Forward if necessary (gravity compensation, custom system characterization).
- Calculating Velocity Feed-Forward (kF) gain if applicable (Velocity Closed Loop, Motion Profile, Motion Magic).

The first two are covered in section “Confirm Sensor Resolution/Velocity”. Calculating feed forward is done in the next section.

2.25.3 Arbitrary Feed Forward

The Arbitrary Feed Forward is a strategy for adding any arbitrary values to the motor output regardless of control mode. It can be used for gravity compensation, custom velocity and acceleration feed forwards, static offsets, and any other term desired.

Note: When setting and tuning closed-loop gains, Arbitrary Feed Forward should be set *first*, before any other values. The Arbitrary Feed Forward will change the relationship between your closed-loop gains and the output of your system, and thus result in different gains needed for a well-tuned mechanism.

Note: Unlike other closed-loop gains, the Arbitrary Feed Forward is passed in as an additional `set()` parameter instead of as a persistent configuration parameter. This is because typical use-cases for Arbitrary Feed Forward frequently change the value dynamically.

Warning: Arbitrary Feed Forward and Auxiliary Closed Loop cannot be used simultaneously *except* when using Motion Profile Arc.

Do I need to use Arbitrary Feed Forward?

We recommend using Arbitrary Feed Forward in any of the following scenarios:

- A mechanism affected by gravity (elevator, arm, etc.).
- Custom system characterization (such as acceleration feed forward).
- Any scenario requiring a static offset.

Note: Units for the arbitrary feedforward term are [-1,+1].

Setting Arbitrary Feed Forward

Arbitrary Feed Forward is passed as an optional parameter in a `set()` call or VI. The value must be set on every call, just like the primary set value.

Example code:

```
_motorcontroller.set(ControlMode.MotionMagic, targetPos, DemandType.  
    ArbitraryFeedForward, feedforward);
```

LabVIEW snippet (drag and drop):

Common Feed Forward Uses/Calculations

Below are some common uses and calculations for Arbitrary Feed Forward.

Gravity Offset (Elevator)

In the case of a traditional elevator mechanism, there is a constant force due to gravity affecting the mechanism. Because the force is constant, we can determine a constant offset to keep the elevator at position when error is zero.

Use either the Phoenix Tuner Control Tab or Joystick control in your robot code to apply output to the elevator until it stays at a position without moving. Use Phoenix Tuner (plotter or Self-test Snapshot) to measure the output value - this is the Arbitrary Feed Forward value needed to offset gravity.

If we measure a motor output of 7% to keep position, then our java code for Arbitrary Feed Forward with Motion Magic would look like this:

```
double feedforward = 0.07;
_motorcontroller.set(ControlMode.MotionMagic, targetPos, DemandType.
    ArbitraryFeedForward, feedforward);
```

Tip: If your elevator mechanism will change weight while in use (i.e. pick up a heavy game piece), it is helpful to measure gravity offsets at each expected weight and switch between Arbitrary Feed Forward values as needed.

Gravity Offset (Arm)

In the case of an arm mechanism, the force due to gravity will change as the arm moves through its range of motion. In order to compensate for this, we will need to measure a gravity offset at the highest force (arm at horizontal position) and then scale the value with trigonometry.

To start, use either the Phoenix Tuner Control Tab or Joystick control in your robot code to apply output to the arm until it stays at the horizontal position without moving. Use Phoenix Tuner (plotter or Self-test Snapshot) to measure the output value - this is the base component of our Arbitrary Feed Forward value.

For scaling the value, the cosine term of [trigonometry](#) matches the scaling we need for our rotating arm. The cosine term is at maximum value (+1) when at horizontal (0 degrees or radians) and is at 0 when the arm is vertical (90 degrees or $\pi/2$ radians). To use this cosine

value as a scalar, we will need to determine our current angle. This requires knowing the current arm position and number of position ticks per degree, then converting to units of radians.

Note: Trigonometry uses 0 for the angle at horizontal. To account for this, we need to subtract the measured horizontal position value before we calculate our angle. This means we will have a positive angle above horizontal and a negative angle below horizontal.

Warning: The java cosine function requires units to be in radians.

```
int kMeasuredPosHorizontal = 840; //Position measured when arm is horizontal
double kTicksPerDegree = 4096 / 360; //Sensor is 1:1 with arm rotation
int currentPos = _motorcontroller.getSelectedSensorPosition();
double degrees = (currentPos - kMeasuredPosHorizontal) / kTicksPerDegree;
double radians = java.lang.Math.toRadians(degrees);
double cosineScalar = java.lang.Math.cos(radians);

double maxGravityFF = 0.07;
_motorcontroller.set(ControlMode.MotionMagic, targetPos, DemandType.
    ArbitraryFeedForward, maxGravityFF * cosineScalar);
```

2.25.4 Calculating Velocity Feed Forward gain (kF)

A typical strategy for estimating the necessary motor output is to take the target velocity and multiplying by a tuned/calculated scalar. More advanced feed forward methods (gravity compensation, custom velocity and acceleration feed forwards, static offsets, etc.) can be done with the arbitrary feed forward features from the previous section..

Note: The velocity feed forward (kF) is different from the Arbitrary Feed Forward in that it is a specialized feed forward designed to approximate the needed motor output to achieve a specified velocity.

Do I need to calculate kF?

If using any of the control modes, we recommend calculating the kF:

- Velocity Closed Loop: kF is multiplied by target velocity and added to output.
- Current (Draw) Closed Loop: kF is multiplied by the target current-draw and added to output.
- MotionMagic/ MotionProfile / MotionProfileArc: kF is multiplied by the runtime-calculated target and added to output.

Note: When using position closed loop, it is generally desired to use a kF of '0'. During this mode target position is multiplied by kF and added to motor output. If providing a feedforward

is necessary, we recommend using the arbitrary feed forward term (4 param Set) to better implement this.

How to calculate kF

Using Tuner (Self-test Snapshot or Plotter), we've measured a peak velocity of **9326** native units per 100ms at 100% output. This can also be retrieved using `getSelectedSensorVelocity` (routine or VI).

However, many mechanical systems and motors are not perfectly linear (though they are close). To account for this, we should calculate our feed forward using a measured velocity around the percent output we will usually run the motor.

For our mechanism, we will typically be running the motor ~75% output. We then use Tuner (Self-test Snapshot or Plotter) to measure our velocity - in this case, we measure a velocity of **7112** native units per 100ms.

Now let's calculate a Feed-forward gain so that 75% motor output is calculated when the requested speed is **7112** native units per 100ms.

$F\text{-gain} = (75\% \times 1023) / 7112$ $F\text{-gain} = 0.1079$

Let's check our math, if the target speed is **7112** native units per 100ms, Closed-loop output will be $(0.1079 \times 7112) \Rightarrow 767.38$ (75% of full forward).

Note: The output of the PIDF controller in Talon/Victor uses 1023 as the "full output".

Note: The kF feature and arbitrary feed-forward feature are not the same. Arbitrary feed-forward is a supplemental term [-1,1] the robot application can provide to add to the output via the `set()` routine/VI.

2.25.5 Motion Magic / Position / Velocity / Current Closed Loop Closed Loop

Closed-looping the position/velocity value of a sensor is explained in this section. This section also applies to the current (draw) closed loop mode.

Relevant source examples can be found at:

- <https://github.com/CrossTheRoadElec/Phoenix-Examples-Languages>
- <https://github.com/CrossTheRoadElec/Phoenix-Examples-LabVIEW>

The general steps are:

- Selecting the sensor type (see previous Bring-Up sections)
- Confirm motor and sensor health (see previous Bring-Up section on sensor)
- Confirm sensor phase (see previous Bring-Up sections)
- Collect max sensor velocity information (see calculating kF section)
- Bring up plotting interface so you can visually see sensor position and motor output. This can be done via Tuner Plotter, or through LabVIEW/SmartDash/API plotting.

- Configure gains and closed-loop centric configs.

Note: If you are using current closed-loop, than a sensor is not necessary.

Note: Current closed loop is not available on Victor SPX, it is only available on Talon SRX.

Once these previous checks are done, continue down to the gain instructions.

Note: This assumes all previous steps have been followed correctly.

1. Checkout the relevant example from CTREs GitHub.
2. Set all of your gains to zero. Use either API or Phoenix Tuner.
3. If not using Position-Closed loop mode, set the k_F to your calculated value (see previous section).
4. If using Motion Magic, set your initial cruise velocity and acceleration (section below).
5. Deploy the application and use the joystick to adjust your target. Normally this requires holding down a button on the gamepad (to enter closed loop mode).
6. Plot the sensor-position to assess how well it is tracking. This can be done with WPI plotting features, or with Phoenix Tuner.

In this example the mechanism is the left-side of a robot's drivetrain. The robot is elevated such that the wheels spin free. In the capture below we see the sensor position/velocity (blue) and the Active Trajectory position/velocity (brown/orange). At the end of the movement the closed-loop error (which is in raw units) is sitting at ~ 1400 .units. Given the resolution of the sensor this is approximately 0.34 rotations (4096 units per rotation). Another note is that when the movement is finished, you can freely back-drive the mechanism without motor-response (because PID gains are zero).

Setting Motion Magic Cruise Velocity And Acceleration

The recommended way to do this is to take your max sensor velocity (previous section).

Suppose your `kMaxSensorVelocity` is **9326** units per 100ms. A reasonable initial cruise velocity may be half of this velocity, which is **4663**.

Config **4663** to be the `cruiseVelocity` via `configMotionCruiseVelocity` routine/VI.

Next lets set the acceleration, which is in velocity units per second (where velocity units = change in sensor per 100ms). This means that if we choose the same value of **4663** for our acceleration, than Motion Magic will ensure it takes one full second to reach peak cruise velocity.

In short set the acceleration to be the same **4663** value via `configMotionAcceleration` routine/VI.

Later you can increase these values based on the application requirements.

Dialing kP

Next we will add in P-gain so that the closed-loop can react to error. In the previous section, after running the mechanism with just F-gain, the servo appears to settle with an error or ~1400.

Given an error of (~1400.), suppose we want to respond with another 10% of throttle. Then our starting kP would be....

$(10\% \times 1023) / (1400) = 0.0731$ Now let's check our math, if the Talon SRX sees an error of 1400 the P-term will be $1400 \times 0.0731 = 102$ (which is about 10% of 1023) $kP = 0.0731$

Apply the P -gain programmatically using your preferred method. Now retest to see how well the closed-loop responds to varying loads.

Retest the maneuver by holding button 1 and sweeping the gamepad stick. At the end of this capture, the wheels were hand-spun to demonstrate how aggressive the position servo responds. Because the wheel still back-drives considerably before motor holds position, the P-gain still needs to be increased.

Double the P-gain until the system oscillates (by a small amount) or until the system responds adequately.

After a few rounds the P gain is at 0.6.

Scope captures below show the sensor position and target position follows visually, but back-driving the motor still shows a minimal motor response.

After several rounds, we've landed on a P gain value of 3. The mechanism overshoots a bit at the end of the maneuver. Additionally, back-driving the wheel is very difficult as the motor-response is immediate (good).

Once settles, the motor is back-driven to assess how firm the motor holds position.

The wheel is held by the motor firmly.

Dialing kD

To resolve the overshoot at the end of the maneuver, D-gain is added. D-gain can start typically at 10 X P-gain.

With this change the visual overshoot of the wheel is gone. The plots also reveal reduced overshoot at the end of the maneuver.

Dialing kI

Typically, the final step is to confirm the sensor settles very close to the target position. If the final closed-loop error is not quite close enough to zero, consider adding I-gain and I-zone to ensure the Closed-Loop Error ultimately lands at zero (or close enough).

In testing the closed-loop error settles around 20 units, so we'll set the Izone to 50 units (large enough to cover the typical error), and start the I-gain at something small (0.001).

Keep doubling I-gain until the error reliably settles to zero.

With some tweaking, we find an I-gain that ensures maneuver settles with an error of 0.

If using Motion Magic, the acceleration and cruise-velocity can be modified to hasten/dampen the maneuver as the application requires.

2.25.6 Auxiliary Closed Loop PID[1] Walkthrough

The auxiliary closed loop can be used to provide a differential output component to a multi motor controller system. See [Auxiliary Closed Loop PID\[1\]](#) for an explanation of the Auxiliary Closed Loop feature - below is a step-by-step walkthrough.

Tip: Be sure to look at the examples that are provided. Any example that has Auxiliary in the name or is named “RemoteClosedLoop” makes use of these features.

Examples can be found here: <https://github.com/CrossTheRoadElec/Phoenix-Examples-Languages>

We *strongly* encourage using the examples first, then only implementing PID[1] in your robot code once comfortable with the examples.

As an example, we will use a differential drive train with 2 encoders on each side and a pigeon.

1. Decide which side’s master motor controller is the *ultimate master*, i.e. the Talon/Vector that will calculate both the linear (PID0) and turn (PID1) component. This example will use the right side as the ultimate master side.
2. Configure all remaining motor controllers on the right side to follow the *ultimate master* motor controller.
3. Configure all motor controllers on the left side to **auxiliary follow** the master motor controller

Note: Alternatively, you can configure one motor controller on the left side to auxiliary follow the master motor controller, and the remaining to follow the auxiliary follower. Note this will introduce additional lag (typically 10ms).

Example below on how to follow the ultimate master.

```
_follower.follow(_ultimateMasterTalon, FollowerType.AuxOutput1); //
↳ follower will apply PID[0] - PID[1] while master applies PID[0] +
↳ PID[1], or vice versa
```

4. Configure PID[0] of the ultimate master motor controller. The example will use the sensor sum of the local encoder and of the other side's encoder.
 - This requires having Sum0 Term configured to use the local encoder and Sum1 Term configured to use a RemoteFilter0.

Note: RemoteFilter 0 or 1 has to be configured to capture the other side's encoder using either a RemoteSRX or CANifier.

See [Bring Up: Differential Sensors](#) for information on bringing up the sensors for differential setups.

5. Configure PID[1] of the ultimate master motor controller. The example will use RemoteSensor1 configured to capture the Pigeon's Yaw value.

See [Bring Up: Differential Sensors](#) for information on bringing up the sensors for differential setups, and [Bring Up: Remote Sensors](#) for bringing up Pigeon IMU as a remote sensor.

6. Determine if the master controller should use the output of PID[0] + PID[1] or if it should use PID[0] - PID[1]. This will depend on the polarity of the sensors, which side of the drivetrain is the ultimate master, and the desired corrective motion.

The auxiliary follower will use whichever sign the master does not use in order to control the differential.

7. When closed-looping the drive train, utilize the 4 parameter set method, specifying a setpoint for the sum of the encoders and a setpoint for the Pigeon IMU yaw.

```
_rightMaster.set(ControlMode.Position, forward, DemandType.AuxPID, -
↳ targetAngle); // _targetAngle is in Pigeon units, 8192 units per
↳ 360'
```

LabVIEW snippet below that uses 4 param set.

8. Tune the PID for both the primary and auxiliary PID using the above methods.

Tip: Primary and Auxiliary PID can initially be tuned independently to simplify the tuning process. Tune the primary PID gains while keeping the Auxiliary target constant, then tune the auxiliary PID gains while keeping the primary target constant (ie. using zero-turn movement). The primary and auxiliary gain sets can then be further tuned when executing motion using both PID loops simultaneously.

2.25.7 Motion Profiling Closed Loop

The above guide shows how to dial PID gains for all closed looping, this guide will talk about how to utilize Motion Profiling using a BufferedStream object.

Note: It is strongly recommended to use the MotionProfiling example first to become familiar with Motion Profiling, and only after having used the example should you try to implement it in your own robot code

Tip: The Buffered stream object is a new object introduced in 2019 designed to make motion profiling easier than ever. The legacy API and the examples that use it are still available.

Create a motion profile

Using Excel or a path generating program, you need to create a series of points that specify the target position, velocity, and the time to the next point. If you are using an example, there is an excel sheet inside the example folder that does this for you named *Motion Profile Generator*. Use this to get started on creating motion profiles.

Upload it to the robot

This can be done either by copy-pasting all the points into the robot application as an array or by copy-pasting the file onto the Robot Controller and using a File operation to read it. The Java/C++ examples show copy-pasting the points into an array, and the excel document we provide has a page that automatically generates the array for you to copy paste.

```
public static double [][]Points = new double[][]{
    {0, 0, 25},
    {0.0003472222222222, 1.666666667, 25},
    {0.0015625, 4.166666667, 25},
    {0.0039930555555555, 7.5, 25},
    .
    .
    .
    {9.997569444444445, 5, 25},
    {9.999131944444445, 2.5, 25},
    {9.999826388888889, 0.833333333, 25},
    {10, 0, 25}
};
```

LabVIEW, on the other hand, uses the file operations to read a csv file and feed the points read from it into an array.

Tip: Drag and drop the image above into your Begin.vi block diagram

Note: The above image also has the next step, *Write the points to a Buffered Stream* included in it

Write the points to a Buffered Stream

Now you need to write all the points onto a buffered stream object. This is done by calling the *Write* method and passing a trajectory point that has the specified position and velocity into the object. Be sure that the first point has zeroPos set to true if you wish to zero the position at the start of the profile and that the last point has isLast set to true so the profile recognizes when it's done.

Java example:

```
/* Insert every point into buffer, no limit on size */
for (int i = 0; i < totalCnt; ++i) {

    double direction = forward ? +1 : -1;
    double positionRot = profile[i][0];
    double velocityRPM = profile[i][1];
    int durationMilliseconds = (int) profile[i][2];

    /* for each point, fill our structure and pass it to API */
    point.timeDur = durationMilliseconds;
    point.position = direction * positionRot * Constants.kSensorUnitsPerRotation;
    // Convert Revolutions to Units
    point.velocity = direction * velocityRPM * Constants.kSensorUnitsPerRotation /
    600.0; // Convert RPM to Units/100ms
    point.auxiliaryPos = 0;
    point.auxiliaryVel = 0;
    point.profileSlotSelect0 = Constants.kPrimaryPIDSlot; /* which set of gains
    would you like to use [0,3]? */
    point.profileSlotSelect1 = 0; /* auxiliary PID [0,1], leave zero */
}
```

(continues on next page)

(continued from previous page)

```

        point.zeroPos = (i == 0); /* set this to true on the first point */
        point.isLastPoint = ((i + 1) == totalCnt); /* set this to true on the last
↪point */
        point.arbFeedFwd = 0; /* you can add a constant offset to add to PID[0]
↪output here */

        _bufferedStream.Write(point);
    }

```

Call startMotionProfile

With the Buffered Stream object fully written to, call startMotionProfile and the motor controller will begin executing once the specified number of points have been buffered into it. Do **not** call Set after this, the motor controller will execute on its own.

Note: Ensure MotorSafety is **Disabled**. Using the new API with MotorSafety enabled causes undefined behavior. If you wish to use MotorSafety with motion profiling, use the Legacy API.

Check isMotionProfileFinished

After having started the motion profile, you should check when the profile is done by polling *IsMotionProfileFinished* until it returns true. Once it is true, you know the profile has reached its last point and is complete, so you can move on to the next action.

```

if (_master.isMotionProfileFinished()) {
    Instrum.println("MP finished");
}

```

2.25.8 Motion Profiling Arc Closed Loop

In addition to the motion profile mode, there is a similar control mode that integrates auxiliary closed loop features. This is called Motion Profile Arc control mode, and utilizes everything that's been covered in the previous sections.

Below is a guide on how to get Motion Profiling Arc up and running, using the new Buffered Stream API.

Note: This is also an example that is available on [our examples repo](#)

Note: The steps for using motion profile arc are very similar and reference the steps for creating a normal motion profile. Read them first

Steps for using Motion Profile Arc:

1. Configure all the motor controllers to use the correct sensors
 - This involves bringing up all the sensors on their respective CAN devices

- *Bring Up: Remote Sensors*
 - *Bring Up: Talon FX/SRX Sensors*
 - This also requires setting up remote sensors and auxiliary closed loops, as detailed in the sections above
2. Create a motion profile. This is the most unique step from a normal motion profile because it will integrate the auxiliary position variable in some way with the profile. If you wish to just make sure the robot is driving straight, generate a normal profile and zero the auxiliary position.
 3. Upload the points to the robot. This is done the same way as for a normal motion profile
 4. Write the points to a Buffered Stream object. This is also done the same way, but be sure to include the **auxiliary position** and **auxiliary velocity** points as well as setting **useAuxPID** to *true*
 5. Call startMotionProfile. Everything regarding normal motion profile is the same as motion profile arc, except that you also need to pass ControlMode.MotionProfileArc as the motion profile control mode
 6. Wait until isMotionProfileFinished returns true. This is the same as a normal motion profile.

2.25.9 Mechanism is Finished Command

Often it is necessary to move a mechanism to a setpoint and ensure that it has properly reached its final position before moving on to the next command. A proper implementation requires the following:

- waiting long enough to ensure CAN framing has provided fresh data. See setStatus-FramePeriod() to modify update rates.
- waiting long enough to ensure mechanism has physically settled. Otherwise closed-loop overshoot (due to inertia) will not be corrected.

Warning: If using Motion Magic control mode, robot code should additionally poll getActiveTrajectoryPosition() routine/VI to determine when final target position has been reached. This is because the closed-loop error corresponds how well the position profile is tracking, not when profiled maneuver is complete.

The general requirements are to periodically monitor the closed-loop error provided the following:

- The latest closed-loop error (via API).
- The **threshold that the closed-loop error must be within** to be considered *acceptable*.
- *How long the closed-loop error has been acceptable.*
- The **threshold of how long the error must be acceptable** before moving on to the next command.

An example of this is shown below in Java, within a class that implements the Command interface

```

int kErrThreshold = 10; // how many sensor units until its close-enough
int kLoopsToSettle = 10; // how many loops sensor must be close-enough
int _withinThresholdLoops = 0;

// Called repeatedly when this Command is scheduled to run
@Override
protected void execute() {
    /* Check if closed loop error is within the threshld */
    if (talon.getClosedLoopError() < +kErrThreshold &&
        talon.getClosedLoopError() > -kErrThreshold) {

        ++_withinThresholdLoops;
    } else {
        _withinThresholdLoops = 0;
    }
}

// Make this return true when this Command no longer needs to run execute()
@Override
protected boolean isFinished() {
    return (_withinThresholdLoops > kLoopsToSettle);
}

```

Warning: If using Motion Magic control mode, robot code should additionally poll `getActiveTrajectoryPosition()` routine/VI to determine when final target position has been reached. This is because the closed-loop error corresponds how well the position profile is tracking, not when profiled maneuver is complete.

2.25.10 Closed-Loop Configurations

The remaining closed-loop centric configs are listed below.

General Closed-Loop Configs

Name	Description
PID 0 Primary Feedback Sensor	Selects the sensor source for PID0 closed loop, soft limits, and value reporting for the SelectedSensor API.
PID 0 Primary Sensor Coefficient	Scalar (0,1] to multiply selected sensor value before using. Note this will reduce resolution of the closed-loop.
PID 1 Aux Feedback Sensor	Select the sensor to use for Aux PID[1].
PID 1 Aux Sensor Coefficient	Scalar (0,1] to multiply selected sensor value before using. Note that this will reduce the resolution of the closed-loop.
PID 1 Polarity	False: motor output = PID[0] + PID[1], follower = PID[0] - PID[1]. True : motor output = PID[0] - PID[1], follower = PID[0] + PID[1]. This only occurs if follower is an auxiliary type.
Closed Loop Ramp	How much ramping to apply in seconds from neutral-to-full. A value of 0.100 means 100ms from neutral to full output. Set to 0 to disable. Max value is 10 seconds.

Closed-Loop configs per slot (four slots available)

Name	Description
kF	Feed Fwd gain for Closed loop. See documentation for calculation details. If using velocity, motion magic, or motion profile, use $(1023 * \text{duty-cycle} / \text{sensor-velocity-sensor-units-per-100ms})$
kP	Proportional gain for closed loop. This is multiplied by closed loop error in sensor units. Note the closed loop output interprets a final value of 1023 as full output. So use a gain of '0.25' to get full output if err is 4096u (Mag Encoder 1 rotation)
kI	Integral gain for closed loop. This is multiplied by closed loop error in sensor units every PID Loop. Note the closed loop output interprets a final value of 1023 as full output. So use a gain of '0.00025' to get full output if err is 4096u (Mag Encoder 1 rotation) after 1000 loops
kD	Derivative gain for closed loop. This is multiplied by derivative error (sensor units per PID loop). Note the closed loop output interprets a final value of 1023 as full output. So use a gain of '250' to get full output if derr is 4096u per (Mag Encoder 1 rotation) per 1000 loops (typ 1 sec)
Loop Period Ms	Number of milliseconds per PID loop. Typically, this is 1ms.
Allowable Error	If the closed loop error is within this threshold, the motor output will be neutral. Set to 0 to disable. Value is in sensor units.
I Zone	Integral Zone can be used to auto clear the integral accumulator if the sensor pos is too far from the target. This prevent unstable oscillation if the kI is too large. Value is in sensor units.
Max Integral Accum	Cap on the integral accumulator in sensor units. Note accumulator is multiplied by kI AFTER this cap takes effect.
Peak Output	Absolute max motor output during closed-loop control modes only. A value of '1' represents full output in both directions.

Motion Magic Closed-Loop Configs

Name	Description
Acceleration	Motion Magic target acceleration in (sensor units per 100ms) per second.
Cruise Velocity	Motion Magic maximum target velocity in sensor units per 100ms.
S-Curve Strength	Zero to use trapezoidal motion during motion magic. [1,8] for S-Curve, higher value for greater smoothing.

Motion Profile Configs

Name	Description
Base Trajectory Period	Base value (ms) ADDED to every buffered trajectory point. Note that each trajectory point has an individual duration (0-127ms). This can be used to uniformly delay every point.
Trajectory Interpolation Enable	Set to true so Motion Profile Executor to linearize the target position and velocity every 1ms. Set to false to match 2018 season behavior (no linearization). This feature allows sending less points over time and still having resolute control Default is set to true.

2.26 Faults

“Faults” are status indicators on CTRE CAN Devices that indicate a certain behavior or event has occurred. Faults do not directly affect the behavior of a device, rather they indicate the device’s current status and highlight potential issues.

Faults are stored in two fashions. There are “live” faults that are reported in real-time, and “sticky” faults which assert persistently and stay asserted until they are manually cleared (like trouble codes in a vehicle).

Note: Sticky Faults can be cleared in Tuner and via API.

Note: Faults and Sticky Faults can be polled using Tuner-Self-test Snapshot or via API.

Tip: Motor Controllers have a sticky fault to detect if device reset during robot-enable. This is useful for detecting breaker events.

2.26.1 Polling Faults in the API

LabVIEW

The GET STATUS VI can be used to retrieve sticky flags, and clear them.

C++/Java

The APIs `getFaults()` and `getStickyFaults()` can be used to check the latest received faults. `clearStickyFaults()` can be used to clear all sticky fault flags.

2.26.2 PCM Faults

Below is the list of common PCM Faults and Resolutions.

Problem	Behavior	Resolution	CAN State	Robot State
Sticky Fault	PCM will slow blink orange . PCM has previously encountered (but is not actively having) a Solenoid Fault or Compressor Fault . Sticky Fault clears via user command over the CAN bus. Sticky Fault does NOT clear on power cycle.	1. Access PDP logger 2. Identify the most recent fault (Solenoid Fault or Compressor Fault) 3. Respond to the fault via the Fault Resolution Table 4. Clear the sticky fault via CAN	Good	Disabled
Solenoid Fault	PCM will blink the number of the faulted solenoid followed by a pause. Fault clears on power cycle.	1. Check faulted solenoid 2. Remove damaged solenoids 3. Remove any metal debris 4. Power cycle 5. Clear sticky fault	Good	NA
Compressor Fault	PCM will blink red in 2 second intervals. Compressor will allow new run attempt every 5 seconds. Fault clears on power cycle OR successful enabling of compressor	1. Check for short across compressor ports 2. Remove any metal debris 3. Clear sticky fault	Good	Enabled
No CAN Comm.	No PCM functionality	1. Connect CAN cable 2. Apply termination resistor 3. Power roboRIO	Bad	NA

2.27 Common Device API

2.27.1 Typical Device Utilization

Configuration	CAN 2.0	CAN FD (CANivore on Phoenix v5.21.1)
Talon FX	4.6%	2.0%
Pigeon 2.0	5.5%	2.5%
CANdle	2.2%	1.0%
CANcoder	1.8%	0.9%
Swerve Drive (8x Talon FX, 4x CANcoder, 1x Pigeon 2.0)	49.7%	22.2%

Note: Phoenix's Diagnostic server can add anywhere from 0 to 5% CAN bus utilization.

Note: These values are base bus utilizations without changing any status frame periods.

Tip: Users should keep the bus utilization below 90% for proper functionality.

Note: CANDLE's device utilization is without LED usage. Animating or setting LEDs will increase bus utilization.

2.27.2 Setting Status Frame Periods

All Phoenix devices have a `setStatusFramePeriod()` routine/VI that allows for tweaking the frame periods of each status group. The status group contents and default updates rates are listed below.

Status Groups

Motor Controllers

Status 1 (Default Period 10ms):

- Applied Motor Output
- Fault Information
- Limit Switch Information

Tip: Motor controllers that are followers can have slower update rates for this group without impacting performance.

Status 2 (Default Period 20ms):

- Selected Sensor Position (PID 0)
- Selected Sensor Velocity (PID 0)
- Brushed Supply Current Measurement
- Sticky Fault Information

Tip: Motor controllers that are followers can have slower update rates for this group without impacting performance.

Status 3 (Default Period >100ms):

- Quadrature Information

Status 4 (Default Period >100ms):

- Analog Input
- Supply Battery Voltage
- Controller Temperature

Status 8 (Default Period >100ms):

- Pulse Width Information

Status 10 (Default Period >100ms):

- Motion Profiling/Motion Magic Information

Status 12 (Default Period >100ms):

- Selected Sensor Position (Aux PID 1)
- Selected Sensor Velocity (Aux PID 1)

Status 13 (Default Period >100ms):

- PID0 (Primary PID) Information

Status 14 (Default Period >100ms):

- PID1 (Auxiliary PID) Information

Status 21 (Default Period >100ms):

- Integrated Sensor Position (Talon FX)
- Integrated Sensor Velocity (Talon FX)

Status Brushless Current (Default Period 50ms):

- Brushless Supply Current Measurement
- Brushless Stator Current Measurement

Pigeon IMU

General Status 1 (Default Period >100ms):

- Calibration Status
- IMU Temperature

Conditioned Status 9 (Default Period 10ms):

- Six degree fused Yaw, Pitch, Roll

Conditioned Status 6 (Default Period 10ms):

- Nine degree fused Yaw, Pitch, Roll (requires magnetometer calibration).

Conditioned Status 11 (Default Period 20ms):

- Accumulated Gyro Angles

Conditioned Status 3 (Default Period >100ms):

- Accelerometer derived angles

Conditioned Status 10 (Default Period >100ms):

- Six degree fused Quaternion

Raw Magnetometer Status 4 (Default Period 20ms):

- Unprocessed magnetometer values (x,y,z)

Biased Status 2 Gyro (Default Period >100ms):

- Biased gyro values (x,y,z)

Biased Status 6 Accelerometer (Default Period >100ms):

- Biased accelerometer values (x,y,z)

CANifier

General Status 1 (Default Period >100ms):

- Applied LED Duty Cycles

Conditioned Status 2 (Default Period 10ms):

- Quadrature Information
- General Inputs

Conditioned Status 3 (Default Period >100ms):

- PWM input 0 Information

Conditioned Status 4 (Default Period >100ms):

- PWM input 1 Information

Conditioned Status 5 (Default Period >100ms):

- PWM input 2 Information

Conditioned Status 6 (Default Period >100ms):

- PWM input 3 Information

CANCoder

General Status 1 (Default Period 10ms):

- Position
- Velocity
- Absolute Position

CAN bus Utilization/Error metrics

The **driver station** provides various **CAN bus metrics** under the **lightning bolt** tab.

Utilization is the *percent of bus time that is in use* relative to the total bandwidth available of the 1Mbps Dual Wire CAN bus. So at 100% there is no idle bus time (no time between frames on the CAN bus).

Demonstrated here is **70% bus use** when controlling **16 Talon SRXs**, along with **1 Pneumatics Control Module (PCM) and the Power Distribution Panel (PDP)**.

The “Bus Off” counter increments every time the CAN Controller in the roboRIO enters “bus-off”, a state where the controller “backs off” transmitting until the CAN bus is deemed “healthy” again.

A good method for watching it increment is to short/release the CAN bus High and Low lines together to watch it enter and leave “Bus Off” (counter increments per short). The “TX Full” counter tracks how often the buffer holding outgoing CAN frames (RIO to CAN device) drops a transmit request. This is another common symptom when the roboRIO no longer is connected to the CAN bus.

The “Receive” and “Transmit” signal is shorthand for “Receive Error Counter” and “Transmit Error Counter”.

These signals are straight from the CAN bus, and track the error instances occurred “on the wire” during reception and transmission respectively. These counts should always be zero. Attempt to short the CAN bus and you can confirm that the error counts rise sharply, then decrement back down to zero when the bus is restored (remove short, reconnect daisy chain).

When starting out with the FRC control system and Talon SRXs, it is recommended to watch how these CAN metrics change when CAN bus is disconnected from the roboRIO and other CAN devices to learn what to expect when there is a harness or a termination resistor issue. Determining hardware related vs software related issues is key to being successful when using many CAN devices.

Followers

Motor controllers that are followers can set Status 1 and Status 2 to 255ms(max) using `setStatusFramePeriod()`.

The Follower relies on the master status frame allowing its status frame to be slowed without affecting performance.

This is a useful optimization to manage CAN bus utilization.

2.27.3 Detecting device resets

All Phoenix devices have a `hasResetOccurred()/VI` routine that will return true if device reset has been detected since previous call.

Detecting this is useful for two reasons:

- Reapply any custom status frame periods that were set using `setStatusFramePeriod()`.
- Telemetry / general troubleshooting (in addition to sticky fault, see tip below).

Tip: Motor Controllers have a sticky fault to detect if device reset during robot-enable. This is useful for detecting breaker events.

2.28 Support

2.28.1 GitHub Examples

All documentation and examples can be found in the public organization... <https://github.com/CrossTheRoadElec>

There many examples in all three FRC languages available at... <https://github.com/CrossTheRoadElec/Phoenix-Examples-Languages> <https://github.com/CrossTheRoadElec/Phoenix-Examples-LabVIEW>

2.28.2 Contact information

CTR Staff can be reached out with the contact information available at...

<https://store.ctr-electronics.com/contact-us/>

The best method for contacting support is via our email (support@ctr-electronics.com). This allows for simple sharing of screenshots and supplemental file attachments.

If seeking help troubleshooting hardware issues, please answer the questions under “Warranty” inside the “Support Request form”.

To resolve your issue in an expedient fashion, we need the following:

- What behavior are you seeing versus what are you expecting to observe?
- What procedure are you following to reproduce the issue?
- If using the roboRIO, we need a screenshot of the Phoenix Tuner to confirm firmware version, gain values, etc.
- If using the roboRIO, we need a screenshot of a Self-test Snapshot taken during the undesired behavior.
- Part numbers of all devices involved. For example, if using a sensor, what is the sensor part number?
- Firmware versions of all devices involved.
- If using motor controllers, are they on CAN bus or PWM?
- If using Phoenix, screenshot of the About form in Phoenix Tuner / Phoenix LifeBoat.

2.29 Troubleshooting and Frequently Asked Questions

2.29.1 Driver Station Messages

What do I do when I see errors in Driver Station?

DS Errors should be addressed as soon as they appear. This is because:

- Phoenix API will report if a device is missing, not functioning, has too-old firmware, etc.
- If errors are numerous and typical, then users cannot determine if there is a new problem to address.
- A large stream of errors can bog down the DriverStation/roboRIO. Phoenix Framework has a debouncing strategy to ensure this does not happen, but not all libraries do this.

Phoenix DS errors occur on call. Meaning VIs/API functions must be called in robot code for any errors to occur. When an error does occur, a stack trace will report where in the robot code to look.

The Debouncing Strategy that Phoenix uses is 3 seconds long. Phoenix keys a new error on device ID & function. This is to ensure that all unique errors are logged while making sure the DriverStation/roboRIO does not generate excessive errors.

Driver Station says the firmware is too old.

Use Phoenix Tuner to update the firmware of the device.

Note that the robot application must be restarted for the firmware version check to clear. This can be done by redeploying the robot application or simply restarting the robot.

Driver Station says the firmware could not be retrieved and to check the firmware and ID.

This usually indicates that your **device ID is wrong** in your robot software, or your firmware is **very old**.

Use Phoenix Tuner to check your device IDs and make sure your firmware is up-to-date.

Driver Station Says “ERROR 7 Call Library Function Node...”

This can be seen when the Phoenix libraries are not present on the roboRIO.

This can be fixed by following the process to prepare the roboRIO for *LabVIEW*.

Driver Station Says Variant To Data in ...

This is usually caused by a diagram disable structure around a MotorController or Enhanced-MotorController VI

In order to fix this, you must wire the device reference through the enabled state of the diagram disabled block

2.29.2 PCM

My compressor turns on and I have air pressure, but why isn't my solenoid turning on?

Check the red LED for the Solenoid channel. If the LED turns on as expected, make sure the Solenoid Voltage Jumper is set to the proper voltage (12 or 24 volts).

Warning: If you attempt to drive 12V Solenoids with 24V, you will damage the solenoids. If you attempt to drive 24V Solenoids with 12V, you *may* damage the solenoids.

Why isn't the Compressor turning on? Why does the PCM COMP LED not turn on?

In order for the compressor output to activate, certain conditions have to be met.

- The robot must be enabled.
- Robot software must have a pneumatics related object (compressor or solenoid).
- PCM must be powered/wired to CAN bus.
- PCM's device ID must match robot software.

If any of these conditions are not met, the compressor will not activate. The best method for root-causing wiring or software issues is to check the following conditions and symptoms in **sequential order**.

PCM must be powered.

This can be checked by ensuring the STATUS LED is illuminated. If the STATUS LED is off, recheck the power path from the PDP to the PCM. If using the fused output of the PDP, check the fuse. This can be done by removing the fuse and checking its continuity/DC-resistance, or simply by measuring the voltage across the power/ground wires that connect into the PCM's Vin Weidmuller input (should be approximately battery voltage or ~12V).

PCM must be on CAN Bus

The PCM must be connected to the CAN bus chain. If a PCM does not see a healthy CAN bus it will blink the STATUS LED red (See User's Guide for LED States).

Additionally the PCM will not appear in Phoenix Tuner or will report loss of communication. This is important to check because a red STATUS LED pattern may also reflect a fault condition (if robot is enabled). To distinguish a fault condition, confirm the PCM does appear in the configuration page, and use the Self-test Snapshot to identify which fault condition is occurring.

If these negative symptoms are noticed, recheck CAN bus harness and termination resistors. If several CAN devices are also blinking red then check the CANH/CANL chain. If it's just the PCM then inspect the Weidmuller CAN contacts on the PCM.

If the PCM CAN connection is healthy, then it should slowly blink green (when robot is disabled). It may blink orange instead to signal that a sticky fault has been logged. Use the Self-test Snapshot in Phoenix Tuner to inspect and clear sticky faults.

More information on faults and sticky faults is available under [PCM Faults](#).

Confirm PCM is not faulting.

At this point the PCM should appear in the Phoenix Tuner CAN Devices tab. Using the Self-test Snapshot, determine if any faults are occurring "Now". Checking the sticky faults can also be helpful for identifying recent faults.

 The self test completed successfully.

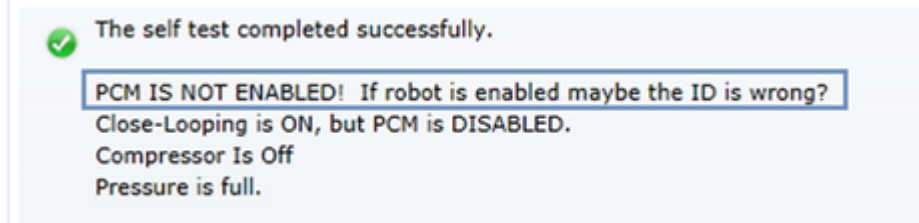

PCM is enabled.
Compressor is close-looped on sensor
Compressor Is Off
Pressure is full.

(Fault)	(Now)	(Sticky)	
Compressor Current	0	0	
Comp Short Circuit	0	1	Most likely the compressor output was shorted
Solenoid Fuse	0	0	
Solen 1	0		
Solen 2	0		
Solen 3	0		
Solen 4	0		
Solen 5	0		
Solen 6	0		
Solen 7	0		
Solen 8	0		

More information on faults and sticky faults is available under [PCM Faults](#).

The Robot must be enabled, Robot Software must create a pneumatics related object.

The PCM should appear in the Phoenix Tuner CAN Devices tab, however when enabling the robot, the STATUS LED may not transition to strobe green. Additionally, when performing the Self-test Snapshot, the report may read “PCM IS NOT ENABLED”

This is typical if the robot is not enabled OR if the robot application did not create any Solenoid or Compressor objects. This is how the programming API signals the intent of using pneumatics, and thus enabling the PCM.

Make sure the robot is truly enabled by looking at the Driver Station.

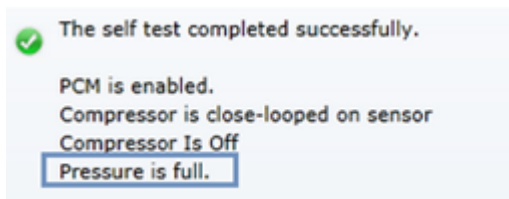

Instructions for creating a Solenoid, DoubleSolenoid or Compressor object in LabVIEW, C++, and Java can be found at <https://docs.wpilib.org>, (search for keyword “PCM”). Creating a single object of any pneumatics related type is sufficient for enabling the PCM (and therefore enabling compressor closed-loop).

Note: In order to create a software object for Solenoid or Compressor, typically the caller may specify the CAN Device ID (not specifying it typically defaults to selecting Device ID zero). This value must match what is specified in Phoenix Tuner. For more information see [Set Device IDs](#).

Tip: Since PCMs default with a device ID of zero, users only using one PCM may prefer to leave the default device ID. PCM Device ID range is allowed to overlap with the device ID of other non-PCM CAN devices.

Pressure Switch must be wired and must signal “not full”.

Even though a robot and PCM are enabled, the compressor output will not activate if the pressure switch is not connected or is indicating full pressure. The only way to inspect this reliably is to perform the Self-test Snapshot in Phoenix Tuner.

If Self-test Snapshot is reading “pressure is full” when the pressure gauge clearly is not full, recheck the wiring on the pressure switch and PCM.

The COMP LED must illuminate green.

If the COMP LED is off then the PCM is not activating the compressor output. The Self-test Snapshot is the best method for determining why. If the PCM is not present in the Phoenix Tuner recheck section the first 2 steps of this process. If the PCM is present and not enabled, recheck the robot program. If the Compressor is not “close-looped on sensor”, then the robot application must be using programming API to disable it. If pressure is erroneously reading “full”, recheck the previous step.

Compressor must be wired and functional.

If the COMP LED is illuminated green but the compressor still is not activating, then there may be a wiring issue between the PCM and the compressor. A voltmeter can be used to confirm that the PCM is applying 12V across the high and low side compressor output, and that 12V is reaching the compressor.

2.30 Errata

2.30.1 CANCoder vH configs don't show up in Tuner

CANCoder vH configs do not show up on the Config Tab in Phoenix Tuner with API versions 5.21.2 and older.

This does not affect the original CANCoder. For information on how to tell what hardware version a CANCoder is, see the [Bring Up: CANCoder - Versions](#) section.

Tip: This is fixed in API version 5.21.3

2.30.2 PigeonIMU Set Fused Heading accepts 1/64th of a degree

The input to setFusedHeading in PigeonIMU uses 64 units per degree instead of degrees.

To work around this, do one of the following:

- Use setYaw instead of setFusedHeading and getYaw instead of getFusedHeading.
- Multiply the desired heading (in degrees) by 64 before calling setFusedHeading.

2.30.3 “Neutral Brake Curr Limit” is often set

Sometimes TalonFX will fault “Neutral Break Curr Limit” on **bootup**.

“Neutral Break Curr Limit” means the TalonFX stator-current-limited *while it was neutral-braking*. This does **not** represent a failure condition as stator-limiting during neutral-brake is an intended feature of the product. Similar sticky faults exist for supply and stator current limits during motor output.

However, sometimes the TalonFX will trip “Neutral Break Curr Limit” when the Talon FX beeps during the boot up procedure.

Workaround: This sticky fault is harmless and *does not impact functionality*. However, if monitoring this flag is required, user application can clear sticky faults after boot-up, then monitor them during operation. Alternatively, user application can monitor the live fault flag during operation.

2.30.4 “Persis Storage Failure” is often set

Sometimes TalonFX will fault “Persis Storage Failure”.

“Persis Storage Failure” means there is a hardware issue with the persistent memory storage in the Talon FX.

However, “Persis Storage Failure” may be reported intermittently by the prom driver in the Talon FX. This can occur due to a known hardware-limitation (errata) with the microcontroller. The Talon firmware *already corrects for this hardware-limitation*, but the sticky fault may *still be reported for diagnostic purposes*. This may change in a future release of firmware.

Workaround: There is no need to work around this issue. Sticky fault can be ignored.

2.30.5 Motion Magic Target does not approach the API requested Target

Under very specific circumstances, the motion magic target position may not approach the final target position requested using Phoenix API. The requirements are:

- Motor Controller firmware is ≤ 22.0
- Motion Magic S-Curve is set to a non-zero value.
- Must be in Motion Magic Control Mode
- Robot application frequently calls the set() method with new values.
- Set point changes exceed 16 bits

Workaround: Any of the following will prevent the issue from occurring:

- Turn off S-Curve OR
- Update firmware to 22.1 OR
- Ensure set point changes are within 16 bits.

Tip: This is fixed in all motor controller versions 22.1

2.30.6 CANivore: Loss of communication under specific circumstances

Under a specific set of circumstances, CANivore will lose communications for 16 seconds and appear frozen (solid LEDs). The requirements are:

- CANivore must be using firmware 22.1.0.1.
- CANivore must be initially connected to USB (Status LED orange or green).
- After initial connection, CANivore must lose connection to **only** USB D+/D- **while maintaining connection** to USB 5V and Ground (Status LED fast-red strobe).

- After loss of D+/D-, CANivore must regain connection to D+/D- while maintaining connection to USB 5V and Ground.

These circumstances do not reproduce the issue in every instance.

The issue was discovered by CTRE staff during routine quality checks.
No customers have reported this failure symptom to date.

Tip: This is fixed in CANivore firmware version 22.2.0.0

2.30.7 LabVIEW Phoenix Open VIs must be chained to guarantee sequential execution

When opening Phoenix objects in LabVIEW, the Open VIs must be chained together so that they execute sequentially. See an example of chaining two Open VIs:

If the Open VIs are not chained together, this can result in:

- Multiple Diagnostic Servers
- Multiple enable signals (enable and disable will conflict, motor controllers will appear to not enable)
- Occasional program crash on deploy

Tip: This is fixed in Phoenix version 5.21.1

2.30.8 Talon FX Remote Filter Device ID Must be 15 or Less

When configuring Talon FX to have a remote sensor, the filter's device ID must be 15 or less. Attempting to set a Remote Filter Device ID >15 in Phoenix Tuner will result in a "DI_Mismatch" error.

When running a robot program, the filter device ID will not be the expected value and so will generate an error that the remote sensor is missing on the bus. The associated fault will also be asserted and can be viewed in self-test snapshot of the Talon FX.

The actual filter device ID set will be truncated to the original set value modulo 15.

Tip: This is fixed in firmware version 21.0.1.0

2.30.9 Java Simulation: WPI_TalonSRX/WPI_VictorSPX Null Pointer Exception

When running simulation, the following error can occur:

```
Error at com.ctre.phoenix.motorcontrol.can.WPI_TalonSRX$OnPeriodicCallback.run(WPI_
↳TalonSRX.java:208): Unhandled exception: java.lang.NullPointerException
    at com.ctre.phoenix.motorcontrol.can.WPI_TalonSRX$OnPeriodicCallback.run(WPI_
↳TalonSRX.java:208)
    at edu.wpi.first.hal.HAL.simPeriodicBefore(HAL.java:41)
    at edu.wpi.first.wpilibj.IterativeRobotBase.loopFunc(IterativeRobotBase.
↳java:281)
    at edu.wpi.first.wpilibj.TimedRobot.startCompetition(TimedRobot.java:117)
    at edu.wpi.first.wpilibj.RobotBase.runRobot(RobotBase.java:335)
    at edu.wpi.first.wpilibj.RobotBase.lambda$startRobot$0(RobotBase.java:387)
    at java.base/java.lang.Thread.run(Thread.java:834)
```

This occurs when multiple WPI_TalonSRX objects have been created with the same device ID or multiple WPI_VictorSPX objects have been created with the same device ID. Find and remove the extra objects from your java code.

2.30.10 HERO firmware compatibility with firmware 4.X

The HERO robot controller still requires v11.X firmware in the motor controllers to function correctly. This will be addressed in a future release (which updates HERO).

The HERO robot controller also still requires v0.41 firmware for Pigeon IMU. This will be addressed in a future release (which updates HERO).

2.30.11 No S-Curve VI in LabVIEW

Pass '412' as the parameter, and the desired S-Curve strength [0,8] as the value.

A value of 0 represents no S-Curving (trapezoidal profiling).

To set the S-Curve strength in LabVIEW, the following LV snippet can be used.

Tip: Drag and drop the bottom image into your LabVIEW Block Diagram.

2.30.12 Stator Current Limit Threshold Configs

The trigger threshold current and time are not honored in 20.0.0 firmware. Stator current limit will trigger when the measured current exceeds the limit (within 1ms).

2.30.13 CANCoder not a remote sensor source

CANCoder is not available as a remote sensor source for Talon FX/SRX and Victor SPX. This will be addressed in a future update.

Tip: This was added in Phoenix v5.17.6. Motor Controller must be updated to 20.1 or newer.

2.30.14 Remote Sensors Not Working with Talon FX

The remote sensor feature does not work with Talon FX.

Tip: This is fixed in firmware version 20.1

2.30.15 Kickoff Temporary Diagnostic Server may not work

The kickoff version of Tuner and temporary diagnostic server has a known issue where CAN bus devices may not show up. **This has been fixed in version 1.6.0.0 of Tuner.** This can be quickly checked by looking at the robot controller install tab of Tuner. If there is no purple “Restart LabVIEW Robot Code” button, Tuner is not up to date and may have this issue. Your version of Tuner should look like the following:

2.30.16 LabVIEW 2020 Deploys failing

During our system level validation, we observed a circumstance where LabVIEW permanent deploys would fail (“Connection disconnected by peer”). We are currently investigating this, but we will tentatively report the following suggestions until we complete our assessment.

- When deploying LabVIEW, we recommend disconnecting Phoenix Tuner to ensure it doesn’t influence LabVIEW’s deploy process.
- If deploys are consistently failing, the running LabVIEW application can be cleared via SSH with `/usr/local/frc/bin/frcKillRobot.sh -t -r` or press the UnDeploy LabVIEW/Diag Server button in Tuner - Robot Controller Install. This should bring the roboRIO into an empty state whereby deploy can be re-attempted.
- Alternatively roboRIO could also be reset using DriverStation “Reboot roboRIO” button. This is effective if roboRIO is running a temporary deployed LV application or temporary diagnostic server.

Tip: This has been resolved in Phoenix v5.17.4.

2.30.17 LabVIEW 2020 Shared-Object Deployment Limitations

When a user hard-deploys an application **while a soft-deployed-session is running**, LabVIEW will sometimes cause deployed shared objects to become inoperable. If this occurs in a project with Phoenix, the project will fail on the deploy step, citing *the network connection was closed by the peer*, and the robot application will be unable to use Phoenix.

To work around this, **press finish on the front panel of Robot Main** before you hard deploy your application.

2.30.18 TalonFX Current Reporting Status Frame Not Available

The Status Frame that TalonFX uses when reporting its supply and stator current is not available under the StatusFrame or StatusFrameEnhanced enum. The enum will be modified to include this frame in a future update. Currently, the following can be done to modify the Current Measurement Status Frame period:

```
_fx.setStatusFramePeriod(0x1240, periodMs); //0x1240 is used to identify the Current_
↳Status Frame
```

Tip: This has been resolved in Phoenix v5.17.6.

2.30.19 Talon FX Thermal Limits Low when using PWM Out-of-the-Box

Talon FX's ship firmware has lower thermal limits than current firmware. If using the Talon FX with PWM control, users may still want to update firmware over CAN to take advantage of the higher thermal limits.

2.30.20 Talon FX does not support Sensor Coefficient

Configuring a sensor coefficient on Talon FX does not do anything.

Tip: This has been resolved in firmware version 20.2.3.0

2.30.21 Talon FX Continuous-Deadbands all the time

Talon FX will always follow a continuous deadband regardless of the mode it's in. This results in double-deadbanding for a follower, which is seen by the applied output of the follower being slightly different than the master. Read more about Continuous Deadbanding inside [Bring Up: Talon FX/SRX and Victor SPX](#).

Tip: This has been resolved in firmware version 20.1.0.0

2.31 Software Release Notes

For the latest release notes, see the full [Release Notes](#).

For the latest firmware versions, see our [Release Repository](#).
